

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

General Description

The MAX9796 combines a high-efficiency Class D, mono audio power amplifier with a mono DirectDrive™ receiver amplifier and a stereo DirectDrive headphone amplifier.

Maxim's 3rd-generation, ultra-low EMI, Class D audio power amplifiers provide Class AB performance with Class D efficiency. The MAX9796 delivers 2.3W into a 4Ω load from a 5V supply and offers efficiencies up to 80%. Active emissions limiting circuitry and spread-spectrum modulation greatly reduce EMI, eliminating the need for output filtering found in traditional Class D devices.

The MAX9796 features a fully differential architecture, a full-bridged output, and comprehensive click-and-pop suppression. The device utilizes a flexible, user-defined mixer architecture that includes an input mixer, volume control, and output mixer. All controls are done through an I²C interface.

The mono receiver amplifier and stereo headphone amplifier use Maxim's patented† DirectDrive architecture, that produces a ground-referenced output from a single supply, eliminating the need for large DC-blocking capacitors, saving cost, space, and component height.

The MAX9796 is available in a 36-bump UCSP™ (3mm x 3mm) package and is specified over the extended -40°C to +85°C temperature range.

†U.S. Patent # 7,061,327

Applications

Cell Phones
Portable Multimedia Players
Handheld Gaming Consoles

Simplified Block Diagram

UCSP is a trademark of Maxim Integrated Products, Inc.

Features

- ◆ Unique Spread-Spectrum Modulation and Active Emissions Limiting Significantly Reduces EMI
- ◆ Up to 3 Stereo Inputs
- ◆ 2.3W Mono Speaker Output (4Ω, V_{DD} = 5V)
- ◆ 50mW Mono Receiver/Stereo Headphone Outputs (32Ω, V_{DD} = 3.3V)
- ◆ High PSRR (68dB at 217Hz)
- ◆ 80% Efficiency (V_{DD} = 3.3V, R_L = 8Ω, P_{OUT} = 600mW)
- ◆ I²C Control—Input Configuration, Volume Control, Output Mode
- ◆ Click-and-Pop Suppression
- ◆ Low Total Harmonic Distortion (0.03% at 1kHz)
- ◆ Current-Limit and Thermal Protection
- ◆ Available in Space-Saving, 36-Bump UCSP (3mm x 3mm)

Continuous Current In/Out of PV _{DD} , PGND, CPV _{DD} , CPGND, OUT_-, HPR, and HPL	±800mA	Lead Temperature (soldering, 10s)	+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V_{DD} = PV_{DD} = CPV_{DD} = 3.3V, GND = PGND = CPGND = 0V, $\overline{\text{SHDN}}$ = V_{DD}, I²C settings (INA gain = +20dB, INB gain = INC gain = 0dB, volume setting = 0dB, mono path gain = 0dB, $\overline{\text{SHDN}}$ = 1, SSM = 1). Speaker load resistors (R_{LSP}) are terminated between OUT+ and OUT-, headphone load resistors are terminated to GND, unless otherwise noted. C1 = C2 = C3 = 1μF. T_A = T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = +25°C.) (Note 1)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS	
GENERAL

Note 1: All devices are 100% production tested at room temperature. All temperature limits are guaranteed by design.

Note 2: Measured at headphone outputs.

Note 3: Amplifier inputs AC-coupled to GND.

Note 4: Testing performed with a resistive load in series with an inductor to simulate an actual speaker load. For $R_L = 8\Omega$ $L = 68\mu H$, $R_L = 4\Omega$ $L = 47\mu H$.

Note 5: Testing performed at room temperature with an 8Ω resistive load in series with $68\mu H$ inductive load connected across BTL outputs for speaker amplifier. Testing performed with 32Ω resistive load connected between OUT- and GND for headphone amplifier. Testing performed with a 32Ω resistive load connected between OUTRx and GND for mono receiver amplifier. Mode transitions are controlled by \overline{SHDN} pin.

Pin Description

BUMP	NAME	FUNCTION
A1	CPV _{DD}	Charge-Pump Power Supply
A2	C1P	Charge-Pump Flying Capacitor Positive Terminal
A3	CPGND	Charge-Pump GND
A4	C1N	Charge-Pump Flying Capacitor Negative Terminal
A5	CPV _{SS}	Charge-Pump Output. Connect to V _{SS} .
A6	HPL	Left Headphone Output
B1, F1, F5	PV _{DD}	Class D Power Supply
B2, E6	I.C.	Internal Connection. Leave unconnected. This pin is internally connected to the signal path. Do not connect together or to any other pin.
B3	VBIAS	Common-Mode Bias
B4	INC1	Input C1. Left input or positive input (see Table 5a).
B5	V _{SS}	Headphone Amplifier Negative Power Supply. Connect to CPV _{SS} .
B6	HPR	Right Headphone Output
C1, F4	OUT+	Positive Speaker Output
C2	SDA	Serial Data Input. Connect a 1k Ω pullup resistor from SDA to V _{DD} .
C5	INC2	Input C2. Right input or negative input (see Table 5a).
C6	OUTRx	Mono Receiver Output
D1, F3	PGND	Power Ground
D2	SCL	Serial Clock Input. Connect a 1k Ω pullup resistor from SCL to V _{DD} .
D5	INB2	Input B2. Right input or negative input (see Table 5a).
D6	V _{DD}	Analog Power Supply
E1, F2	OUT-	Negative Speaker Output
E2	SHDN	Active-Low Hardware Shutdown
E3	INA1	Input A1. Left input or positive input (see Table 5a).
E4	INA2	Input A2. Right input or negative input (see Table 5a).
E5	INB1	Input B1. Left input or positive input (see Table 5a).
F6	GND	Analog Ground

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Typical Application Circuit

MAX9796

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Detailed Description

The MAX9796 ultra-low-EMI, filterless, Class D audio power amplifier features several improvements to switch-mode amplifier technology. The MAX9796 features active emissions limiting circuitry to reduce EMI. Zero dead-time technology maintains state-of-the-art efficiency and THD+N performance by allowing the output FETs to switch simultaneously without cross-conduction. A unique filterless modulation scheme and a spread-spectrum modulation create a compact, flexible, low-noise, efficient audio power amplifier while occupying minimal board space. The differential input architecture reduces common-mode noise pickup with or without the use of input-coupling capacitors. The MAX9796 can also be configured as a single-ended input amplifier without performance degradation.

The MAX9796 features three fully differential input pairs (INA_, INB_, INC_) that can be configured as stereo single-ended or mono differential inputs. I²C provides control for input configuration, volume level, and mixer configuration. DirectDrive allows the headphone and mono receiver amplifiers to output ground-referenced

signals from a single supply, eliminating the need for large DC-blocking capacitors. Comprehensive click-and-pop suppression minimizes audible transients during the turn-on and turn-off of amplifiers.

Class D Speaker Amplifier

Comparators monitor the audio inputs and compare the complementary input voltages to a sawtooth waveform. The comparators trip when the input magnitude of the sawtooth exceeds their corresponding input voltage. The active emissions limiting circuitry slightly reduces the turn-on rate of the output H-bridge by slew-rate limiting the comparator output pulse. Both comparators reset at a fixed time after the rising edge of the second comparator trip point, generating a minimum-width pulse ($t_{ON(MIN)}$, 100ns typ) at the output of the second comparator (Figure 1). As the input voltage increases or decreases, the duration of the pulse at one output increases while the other output pulse duration remains the same. This causes the net voltage across the speaker ($V_{OUT+} - V_{OUT-}$) to change. The minimum-width pulse helps the device to achieve high levels of linearity.

Figure 1. Outputs with an Input Signal Applied

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Operating Modes

Fixed-Frequency Modulation

The MAX9796 features a fixed-frequency modulation mode with a 1.1MHz switching frequency, set through the I²C interface (Table 2). In fixed-frequency modulation mode, the frequency spectrum of the Class D output consists of the fundamental switching frequency and its associated harmonics (see the Wideband Output Spectrum Fixed-Frequency Mode graph in the *Typical Operating Characteristics*).

Spread-Spectrum Modulation

The MAX9796 features a unique, patented spread-spectrum modulation that flattens the wideband spectral components. Proprietary techniques ensure that the

cycle-to-cycle variation of the switching period does not degrade audio reproduction or efficiency (see the *Typical Operating Characteristics*). Select the spread-spectrum modulation mode through the I²C interface (Table 2). In spread-spectrum modulation mode, the switching frequency varies randomly by $\pm 30\text{kHz}$ around the center frequency (1.16MHz). The modulation scheme remains the same, but the period of the sawtooth waveform changes from cycle to cycle (Figure 2). Instead of a large amount of spectral energy present at multiples of the switching frequency, the energy is now spread over a bandwidth that increases with frequency. Above a few megahertz, the wideband spectrum looks like white noise for EMI purposes (see Figure 3).

Figure 3. EMI with 76mm of Speaker Cable

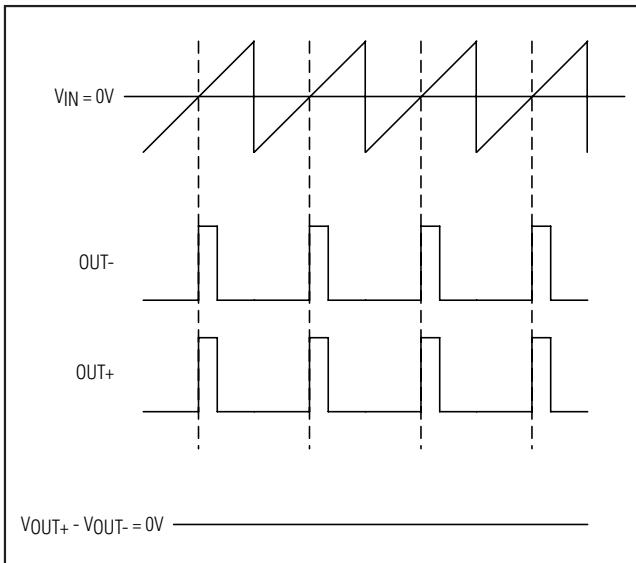

Figure 4. Outputs with No Input Signal

Filterless Modulation/Common-Mode Idle

The MAX9796 uses Maxim's unique, patented modulation scheme that eliminates the LC filter required by traditional Class D amplifiers, improving efficiency, reducing component count, conserving board space and system cost. Conventional Class D amplifiers output a 50% duty-cycle square wave when no signal is present. With no filter, the square wave appears across the load as a DC voltage, resulting in finite load current, increasing power

consumption, especially when idling. When no signal is present at the input of the MAX9796, the outputs switch as shown in Figure 4. Because the MAX9796 drives the speaker differentially, the two outputs cancel each other, resulting in no net idle mode voltage across the speaker, minimizing power consumption.

DirectDrive

Traditional single-supply headphone amplifiers have outputs biased at a nominal DC voltage (typically half the supply) for maximum dynamic range. Large coupling capacitors are needed to block this DC bias from the headphone. Without these capacitors, a significant amount of DC current flows to the headphone, resulting in unnecessary power dissipation and possible damage to both headphone and headphone amplifier.

Maxim's patented DirectDrive architecture uses a charge pump to create an internal negative supply voltage. This allows the headphone outputs of the MAX9796 to be biased at GND, almost doubling dynamic range while operating from a single supply. With no DC component, there is no need for the large DC-blocking capacitors. Instead of two large (220µF, typ) tantalum capacitors, the MAX9796 charge pump requires two small ceramic capacitors, conserving board space, reducing cost, and improving the frequency response of the headphone amplifier. See the Output Power vs. Load Resistance and Charge-Pump Capacitor Size graph in the *Typical Operating Characteristics* for details of the possible capacitor sizes. There is a low DC voltage on the driver outputs

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

due to amplifier offset. However, the offset of the MAX9796 is typically 1.4mV, which, when combined with a 32Ω load, results in less than 44nA of DC current flow to the headphones.

In addition to the cost and size disadvantages of the DC-blocking capacitors required by conventional headphone amplifiers, these capacitors limit the amplifier's low-frequency response and can distort the audio signal. Previous attempts at eliminating the output-coupling capacitors involved biasing the headphone return (sleeve) to the DC bias voltage of the headphone amplifiers. This method raises some issues:

- 1) The sleeve is typically grounded to the chassis. Using the midrail biasing approach, the sleeve must be isolated from system ground, complicating product design.
- 2) During an ESD strike, the driver's ESD structures are the only path to system ground. Thus, the amplifier must be able to withstand the full ESD strike.
- 3) When using the headphone jack as a lineout to other equipment, the bias voltage on the sleeve may conflict with the ground potential from other equipment, resulting in possible damage to the amplifiers.

Charge Pump

The MAX9796 features a low-noise charge pump. The switching frequency of the charge pump is half the switching frequency of the Class D amplifier, regardless of the operating mode. The nominal switching frequency is well beyond the audio range, and thus does not interfere with the audio signals, resulting in an SNR of 93dB. Although not typically required, additional high-frequency noise attenuation can be achieved by increasing the size of C2 (see the *Typical Application Circuit*). The charge pump is active in both speaker and headphone modes.

Signal Path

The audio inputs of the MAX9796 (INA, INB, and INC) are preamplified and then mixed by the input mixer to create three internal signals: left (L), right (R), and mono (M). Tables 5a and 5b show how the inputs are mixed to create L, R, and M. These signals are then independently volume adjusted by the L, R, and M volume control and routed to the output mixer. The output mixer mixes the internal L, R, and M signals to create a variety of audio mixes that are output to the headphone, speaker,

Figure 5. Traditional Amplifier Output vs. MAX9796 DirectDrive Output

and the mono receiver amplifiers. Figure 6 shows the signal path that the audio signals take.

Signal amplification takes place in three stages. In the first stage, the inputs (INA, INB, and INC) are preamplified. The amount by which each input is amplified is determined by the bits INA+20dB (B4 in the Input Mode Control Register) and IN+6dB (B3 in the Global Control Register). After preamplification, they are mixed in the input mixer to create the internal signals L, R and M.

In the second stage of amplification, the internal L, R, and M signals are independently volume adjusted.

Finally, each output amplifier has its own internal gain. The speaker, headphone, and mono receiver amplifiers have fixed gains of 12dB, 3dB and 3dB, respectively.

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Figure 6. Signal Path

Current-Limit and Thermal Protection

The MAX9796 features current limiting and thermal protection to protect the device from short circuits and overcurrent conditions. The headphone amplifier pulses in the event of an overcurrent condition with a pulse every 100 μ s as long as the condition is present. Should the current still be high, the above cycle is repeated. The speaker amplifier current-limit protection clamps the output current without shutting down the output. This can result in a distorted output. Current is limited to 1.6A in the speaker amplifiers and 170mA in the headphone and mono receiver amplifiers.

The MAX9796 has thermal protection that disables the device at +150°C until the temperature decreases to +120°C.

Click-and-Pop Suppression

In conventional single-supply headphone amplifiers, the output-coupling capacitor is a major contributor of audible clicks and pops. Upon startup, the amplifier charges the coupling capacitor to its bias voltage, typically half the supply. Likewise, during shutdown, the capacitor is discharged to GND. This results in a DC shift across the capacitor, which in turn, appears as an audible transient at the speaker. Since the MAX9796

headphone amplifier does not require output-coupling capacitors, this problem does not arise.

In most applications, the output of the preamplifier driving the MAX9796 has a DC bias of typically half the supply. During startup, the input-coupling capacitor is charged to the preamplifier's DC bias voltage, resulting in a DC shift across the capacitor and an audible click-and-pop. An internal delay of 30ms eliminates the click-and-pop caused by the input filter.

Shutdown

The MAX9796 features a 0.1 μ A hard shutdown mode that reduces power consumption to extend battery life and a soft shutdown where current consumption is typically 8.5 μ A. Hard shutdown is controlled by connecting $\overline{\text{SHDN}}$ to GND, disabling the amplifiers, bias circuitry, charge pump, and I²C. In shutdown, the headphone amplifier output impedance is 1.4k Ω and the speaker output impedance is 300k Ω . Similarly, the MAX9796 enters soft shutdown when the $\overline{\text{SHDN}}$ bit = 0 (see Table 2). The I²C interface is active and the contents of the command register are not affected when in soft shutdown. This allows the master to write to the MAX9796 while in shutdown. The I²C interface is completely disabled in hardware shutdown. When the MAX9796 is re-enabled the default settings are applied (see Table 3).

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Figure 7. 2-Wire Serial-Interface Timing Diagram

I²C Interface

The MAX9796 features an I²C 2-wire serial interface consisting of a serial-data line (SDA) and a serial-clock line (SCL). SDA and SCL facilitate communication between the MAX9796 and the master at clock rates up to 400kHz. Figure 7 shows the 2-wire interface timing diagram. The MAX9796 is a receive-only slave device relying on the master to generate the SCL signal. The master, typically a microcontroller, generates SCL and initiates data transfer on the bus. The MAX9796 cannot write to the SDA bus except to acknowledge the receipt of data from the master. The MAX9796 does not acknowledge a read command from the master.

A master device communicates to the MAX9796 by transmitting the proper address followed by the data word. Each transmit sequence is framed by a START (S) or REPEATED START (Sr) condition and a STOP (P) condition. Each word transmitted over the bus is 8 bits long and is always followed by an acknowledge clock pulse.

The MAX9796 SDA line operates as both an input and an open-drain output. A pullup resistor, greater than 500Ω, is required on the SDA bus. The MAX9796 SCL line operates as an input only. A pullup resistor, greater than 500Ω, is required on SCL if there are multiple masters on the bus, or if the master in a single-master system has an open-drain SCL output. Series resistors in line with SDA and SCL are optional. Series resistors protect the digital inputs of the MAX9796 from high-voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus signals.

Figure 8. START, STOP, and REPEATED START Conditions

Bit Transfer

One data bit is transferred during each SCL cycle. The data on SDA must remain stable during the high period of the SCL pulse. Changes in SDA while SCL is high are control signals (see the *START and STOP Conditions* section). SDA and SCL idle high when the I²C bus is not busy.

START and STOP Conditions

A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA while SCL is high (Figure 8). A START condition from the master signals the beginning of a transmission to the MAX9796. The master terminates transmission and frees the bus by issuing a STOP condition. The bus remains active if a REPEATED START condition is generated instead of a STOP condition.

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Early STOP Conditions

The MAX9796 recognizes a STOP condition at any point during data transmission except if the STOP condition occurs in the same high pulse as a START condition.

Slave Address

The MAX9796 is available with one preset slave address (see Table 1). The address is defined as the seven most significant bits (MSBs) followed by the read/write (R/W) bit. The address is the first byte of information sent to the MAX9796 after the START condition. The MAX9796 is a slave device only capable of being written to. The R/W bit should be a zero when configuring the MAX9796.

Acknowledge

The acknowledge bit (ACK) is a clocked 9th bit that the MAX9796 uses to handshake receipt of each byte of data (see Figure 9). The MAX9796 pulls down SDA during the master-generated 9th clock pulse. Monitoring ACK allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the

event of an unsuccessful data transfer, the bus master may reattempt communications.

Write Data Format

A write to the MAX9796 includes transmission of a START condition, the slave address with the R/W bit set to 0 (Table 1), one byte of data to configure the Command Register, and a STOP condition. Figure 10 illustrates the proper format for one frame.

The MAX9796 only accepts write data, but it acknowledges the receipt of the address byte with the R/W bit set high. The MAX9796 does not write to the SDA bus in the event that the R/W bit is set high. Subsequently, the master reads all 1's from the MAX9796. Always set the R/W bit to zero to avoid this situation.

Programming the MAX9796

The MAX9796 is programmed through six control registers. Each register is addressed by the three MSBs (B5–B7) followed by five configure bits (B0–B4) as shown in Table 2. Correct programming of the MAX9796 requires writing to all six control registers. Upon power-on, their default settings are as listed in Table 3.

Input Mode Control

The MAX9796 has three flexible inputs that can be configured as single-ended stereo inputs or differential mono inputs. All input signals are summed into three unique signals, Left (L), Right (R), and Mono (M), which are routed to the output amplifiers. The bit B4 allows the option of boosting low-level signals on INA. B4 can be set as follows:

1 = Input A's gain +20dB for low-level signals such as FM receivers.

0 = Input A's gain is either 0dB or +6dB as set by IN+6dB (bit B3 of the Control Register).

Tables 5a and 5b show how the inputs—INA, INB, and INC—are mixed to create the internal signals left (L), right (R), and mono (M).

Mono/Left/Right Volume Control

The MAX9796 has separate volume control for each of the internal signals: left (L), right (R), and mono (M). The final gain of each signal is determined by the way the

following bits are set: MVOL, LVOL, RVOL, INA+20dB, IN+6dB, and MONO+6dB. Table 7 shows how to configure the L, R, and M amplifiers for specific gains.

Output Mode Control

MONO+6dB in the Output Mode Control register allows an extra 6dB of gain on the internal mono signal:

1 = Additional 6dB of gain is applied to the internal Mono (M) signal path.

0 = No additional gain is applied to the Internal Mono (M) signal path.

The MAX9796 has four output amplifiers: a mono receiver amplifier, a stereo DirectDrive headphone amplifier, and one mono Class D amplifier.

BIT	NAME	FUNCTION
B4	$\overline{\text{SHDN}}$	1 = Normal operation. 0 = Low-power shutdown mode. I ² C settings are saved.
B3	IN+6dB	1 = All input signals are boosted by 6dB. 0 = All input signals are passed unamplified. This bit does not affect INA if the INA+20dB bit (B4 of the Input Mode Control Register) is set to 1, in which case INA is boosted by 20dB.
B2	MUTE	1 = Mute all outputs. 0 = All outputs are active.
B1	SSM	1 = Spread-spectrum Class D modulation. 0 = Fixed-frequency Class D modulation.
B0	MONO	1 = Speaker outputs L+R in modes 7, 8, 12, and 13 (see Table 9). 0 = Speaker outputs L in modes 7, 8, 12, and 13 (see Table 9).

Applications Information

Class D Filterless Operation

Traditional Class D amplifiers require an output filter to recover the audio signal from the amplifier's PWM output. The filters add cost, increase the solution size of the amplifier, and can decrease efficiency. The traditional PWM scheme uses large differential output swings ($2 \times V_{DD(P-P)}$) and causes large ripple currents. Any parasitic resistance in the filter components results in a loss of power, lowering the efficiency.

The MAX9796 does not require an output filter. The device relies on the inherent inductance of the speaker coil and the natural filtering of both the speaker and the human ear to recover the audio component of the square-wave output. Eliminating the output filter results in a smaller, less costly, more efficient solution.

Because the switching frequency of the MAX9796 speaker output is well beyond the bandwidth of most

speakers, voice coil movement due to the square-wave frequency is very small. Although this movement is small, a speaker not designed to handle the additional power may be damaged. For optimum results, use a speaker with a series inductance $>10\mu\text{H}$. Typical 8Ω speakers, for portable audio applications, exhibit series inductances in the range of $20\mu\text{H}$ to $100\mu\text{H}$.

Input Amplifier

Differential Input

The MAX9796 features a programmable differential input structure, making it compatible with many CODECs, and offering improved noise immunity over a single-ended input amplifier. In devices such as cellular phones, high-frequency signals from the RF transmitter can be picked up by the amplifier's input traces. The signals appear at the amplifier's inputs as common-mode noise. A differential input amplifier amplifies the difference of the two inputs and any signal common to both is cancelled.

2.3W, High-Power Class D Audio Subsystem with DirectDrive Headphone Amplifiers

Charge-Pump Capacitor Selection

Use capacitors with an ESR less than 100mΩ for optimum performance. Low-ESR ceramic capacitors minimize the output resistance of the charge pump. Most surface-mount ceramic capacitors satisfy the ESR requirement. For best performance over the extended temperature range, select capacitors with an X7R dielectric or better. Table 12 lists suggested manufacturers.

Flying Capacitor (C1)

The value of the flying capacitor (C1) affects the output resistance of the charge pump. A C1 value that is too small degrades the device's ability to provide sufficient current drive, which leads to a loss of output voltage. Increasing the value of C1 reduces the charge-pump output resistance to an extent. Above 1μF, the on-resistance of the switches and the ESR of C1 and C2 dominate.

Output Capacitor (C2)

The output capacitor value and ESR directly affect the ripple at CPV_{SS}. Increasing the value of C2 reduces output ripple. Likewise, decreasing the ESR of C2 reduces both ripple and output resistance. Lower capacitance values can be used in systems with low maximum output power levels. See the Output Power vs. Load Resistance and Charge-Pump Capacitor Size graph in the *Typical Operating Characteristics*.

CPV_{DD} Bypass Capacitor (C3)

The CPV_{DD} bypass capacitor (C3) lowers the output impedance of the power supply and reduces the impact of the MAX9796's charge-pump switching transients. Bypass CPV_{DD} with C3 to PGND and place it physically close to the CPV_{DD} and PGND. Use a value for C3 that is equal to C1.

Supply Bypassing, Layout, and Grounding

Proper layout and grounding are essential for optimum performance. Use large traces for the power-supply inputs and amplifier outputs to minimize losses due to

parasitic trace resistance. Large traces also aid in moving heat away from the package. Proper grounding improves audio performance, minimizes crosstalk between channels, and prevents any switching noise from coupling into the audio signal. Connect PGND and GND together at a single point on the PCB. Route all traces that carry switching transients away from GND and the traces/components in the audio signal path.

Connect all of the power-supply inputs (CPV_{DD}, V_{DD}, and PV_{DD}) together. Bypass CPV_{DD} with a 1μF capacitor to CPGND. Bypass V_{DD} with a 1μF capacitor to GND. Bypass PV_{DD} with a 1μF capacitor in parallel with a 0.1μF capacitor to PGND. Place the bypass capacitors as close as possible to the MAX9796. Place a bulk capacitor between PV_{DD} and PGND, if needed.

Use large, low-resistance output traces. Current drawn from the outputs increase as load impedance decreases. High output trace resistance decreases the power delivered to the load. Large output, supply, and GND traces allow more heat to move from the MAX9796 to the PCB, decreasing the thermal impedance of the circuit.

UCSP Applications Information

For the latest application details on UCSP construction, dimensions, tape carrier information, PCB techniques, bump-pad layout, and recommended reflow temperature profile, as well as the latest information of reliability testing results, refer to Application Note: UCSP—A Wafer-Level Chip-Scale Package available on Maxim's website at www.maxim-ic.com/ucsp.

UCSP Thermal Consideration

When operating at maximum output power, the UCSP thermal dissipation can become a limiting factor. The UCSP package does not dissipate heat as efficiently as packages with a thermal pad. As a result, in some applications, the thermal performance of the package may limit performance.
