

Dual and Quad Channel Micropower, Single Supply, Rail-to-Rail Input and Output (RRIO) Instrumentation Amplifiers

The ISL28270 and ISL28273 are dual channel micropower instrumentation amplifiers (in-amps) and the ISL28470 is a quad channel in-amp optimized for single supply operation over the +2.4V to +5.5V range.

All three devices feature an Input Range Enhancement Circuit (IREC) which maintains CMRR performance for input voltages equal to the positive supply and down to 50mV above the negative supply rail. The input signal is capable of swinging above the positive supply rail and to 10mV above the negative supply with only a slight degradation of the CMRR performance. The output operation is rail-to-rail.

The ISL28273 is compensated for a minimum gain of 10 or more. For higher gain applications, the ISL28270 and ISL28470 are compensated for a minimum gain of 100. The in-amps have bipolar input devices for best offset and excellent 1/f noise performance. The amplifiers can be operated from one lithium cell or two Ni-Cd batteries.

*Please refer to TB347 for details on reel specifications.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Features

- 150 μ V max offset voltage (ISL28270, ISL28470)
- 600 μ V max offset voltage (ISL28273)
- 2.5nA max input bias current (ISL28270, ISL28470)
- 110dB CMRR
- 0.7 μ V/ $^{\circ}$ C offset voltage temperature coefficient
- 240kHz -3dB bandwidth (G = 100) ISL28270, ISL28470
- 230kHz -3dB bandwidth (G = 10) ISL28273
- Single supply operation
- Rail-to-rail input and output (RRIO)
- Pb-free plus anneal available (RoHS compliant)

Applications

- Battery or solar-powered systems
- Strain gauge
- Sensor signal conditioning
- Medical devices
- Industrial instrumentations

Application Information

Product Description

The ISL28270 and ISL28273 are dual channel micro-power instrumentation amplifiers (in-amps) and the ISL28470 is a quad channel which deliver rail-to-rail input amplification and rail-to-rail output swing. The in-amps also deliver excellent DC and AC specifications while consuming only about 60µA per channel. Because the independent pair of feedback terminals set the gain and adjust the output zero level, the ISL28270, ISL28273 and ISL28470 achieve high CMRR regardless of the tolerance of the gain setting resistors. The ISL28270 and ISL28470 are internally compensated for a minimum gain of 100. The ISL28273 is internally compensated for a minimum gain of 10.

$\overline{\text{EN}}$ pins are available to independently enable or disable a channel. When all channels are off, current consumption is down to typically 4µA on the duals (ISL28270 and ISL28273), and 10µA on the quad (ISL28470).

Input Protection

All input terminals and feedback terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. Input signals originating from low impedance sources should have current limiting resistors in series with the IN+ and IN- pins to prevent damaging currents during power supply sequencing and other transient conditions. The ISL28270 and ISL28470 have additional back-to-back diodes across the input terminals and also across the feedback terminals. If overdriving the inputs is necessary, the external input current must never exceed 5mA. External

series resistors may be used as an external protection to limit excessive external voltage and current from damaging the inputs. On the other hand, the ISL28273 has no clamps to limit the differential voltage on the input terminals allowing higher differential input voltages at lower gain applications. It is recommended, however, that the terminals of the ISL28273 are not overdriven beyond 1V to avoid offset drift.

Input Stage and Input Voltage Range

The input terminals (IN+ and IN-) of the in-amps are a single differential pair of bipolar PNP devices aided by an Input Range Enhancement Circuit, IREC, to increase the headroom of operation of the common-mode input voltage. The feedback terminals (FB+ and FB-) also have a similar topology. As a result, the input common-mode voltage range is rail-to-rail regardless of the feedback terminal settings and regardless of the gain settings. They are able to handle input voltages that are at or slightly beyond the supply and close to ground making these in-amps well suited for single 5V down to 2.4V supply systems. There is no need to bias the common-mode input to achieve symmetrical input voltage. It is recommended however that the common-mode input be biased at least 10mV above the negative supply rail to achieve top performance. See "Input Bias Cancellation/Compensation" on page 15.

The IREC enables rail-to-rail input amplification without the problems usually associated with the dual differential stage topology. The IREC ensures that there are no drastic changes in offset voltage over the entire range of the input. See Input Offset Voltage vs Common-Mode Input Voltage on page 8. IREC also cures the abrupt change and even reverse polarity of the input bias current over the whole

range of input. See Input Bias Current vs Common-Mode Input Voltage on page 8.

Input Bias Cancellation/Compensation

All three parts have an Input Bias Cancellation/Compensation Circuit for both the input and feedback terminals (IN+, IN-, FB+ and FB-), achieving a low input bias current throughout the input common-mode range and the operating temperature range. While the PNP bipolar input stages are biased with an adequate amount of biasing current for speed and increased noise performance, the Input Bias Cancellation/Compensation Circuit sinks most of the base current of the input transistors leaving a small portion as input bias current, typically 500pA. In addition, the Input Bias Cancellation/Compensation Circuit maintains a smooth and flat behavior of input bias current over the common mode range and over the operating temperature range. The Input Bias Cancellation/Compensation Circuit operates from input voltages of 10mV above the negative supply to input voltages slightly above the positive supply. See Input Bias Current vs Common-Mode Input Voltage in the “Typical Performance Curves” on page 8.

Output Stage and Output Voltage Range

A Class AB common-source output stage drives the output. The pair of complementary MOSFET devices drive the output VOUT to within a few millivolts of the supply rails. At a 100kΩ load, the PMOS sources current and pulls the output up to 4mV below the positive supply. The NMOS sinks current and pulls the output down to 4mV above the negative supply, or ground in the case of a single supply operation. The current sinking and sourcing capability are internally limited to 29mA. When disabled, the outputs are in a high impedance state.

Gain Setting

VIN, the potential difference across IN+ and IN-, is replicated (less the input offset voltage) across FB+ and FB-. The function of the in-amp is to maintain the differential voltage across FB- and FB+ equal to IN+ and IN-; (FB- - FB+) = (IN+ - IN-). Consequently, the transfer function can be derived. The in-amp gain is set by two external resistors, the feedback resistor RF, and the gain resistor RG.

$$V_{IN} = IN+ - IN-$$

$$V_{OUT} = \left(1 + \frac{R_F}{R_G}\right) V_{IN} \tag{EQ. 1}$$

In Figure 49, the FB+ pin and one end of resistor RG are connected to GND. With this configuration, Equation 1 is only true for a positive swing in VIN; negative input swings will be ignored because the output will be at ground.

FIGURE 49. GAIN IS SET BY TWO EXTERNAL RESISTORS, RF AND RG

Reference Connection

Unlike a three op amp in-amp realization, a finite series resistance seen at the REF terminal does not degrade the high CMRR performance, eliminating the need for an additional external buffer amplifier. Figure 50 uses the FB+ pin to provide a high impedance REF terminal.

FIGURE 50. GAIN SETTING AND REFERENCE CONNECTION

$$V_{IN} = IN+ - IN-$$

$$V_{OUT} = \left(1 + \frac{R_F}{R_G}\right) (V_{IN}) + \left(1 + \frac{R_F}{R_G}\right) (V_{REF}) \tag{EQ. 2}$$

The FB+ pin is used as a REF terminal to center or to adjust the output. Because the FB+ pin is a high impedance input, an economical resistor divider can be used to set the voltage at the REF terminal without degrading or affecting the CMRR performance. Any voltage applied to the REF terminal will shift VOUT by VREF times the closed loop gain, which is set by resistors RF and RG. Note that any noise or unwanted signals on the reference supply will be amplified at the output according to Equation 2. See Figure 50.

The FB+ pin can also be connected to the other end of resistor, RG. See Figure 51. Keeping the basic concept that

the in-amp maintains constant differential voltage across the input terminals and feedback terminals (FB- - FB+) = (IN+ - IN-), the transfer function of Figure 51 can be derived from Equation 3. Note that the VREF gain term is eliminated, and susceptibility to external noise is reduced.

FIGURE 51. REFERENCE CONNECTION WITH AN AVAILABLE VREF

$$V_{IN} = IN+ - IN-$$

$$V_{OUT} = \left[1 + \frac{R_S + R_F}{R_G} \right] + V_{REF} \quad (EQ. 3)$$

$$V_{OUT} = \left(1 + \frac{R_F}{R_G} \right) (V_{IN}) + (V_{REF}) \quad (EQ. 4)$$

A finite resistance R_S in series with the V_{REF} source, adds an output offset of $V_{IN} \cdot (R_S/R_G)$. As the series resistance R_S approaches zero, Equation 3 is simplified to Equation 4 for Figure 51. V_{OUT} is simply shifted by an amount V_{REF} .

External Resistor Mismatches

Because of the independent pair of feedback terminals provided by the in-amps, the CMRR is not degraded by any resistor mismatches. Hence, unlike a three op amp and especially a two op amp in-amp realization, the ISL28270, ISL28273 and ISL28470 reduce the cost of external components by allowing the use of 1% or more tolerance resistors without sacrificing CMRR performance. The CMRR will be typically 110dB regardless of the tolerance of the resistors used. Instead, a resistor mismatch results in a higher deviation from the theoretical gain - gain error.

Gain Error and Accuracy

The gain error indicated in the “Electrical Specifications” table on page 4 is the inherent gain error alone. The gain error specification listed does not include the gain error contributed by the resistors. There is an additional gain error due to the tolerance of the resistors used. The resulting non-ideal transfer function effectively becomes:

$$V_{OUT} = \left(1 + \frac{R_F}{R_G} \right) \times [1 \pm (E_{RG} + E_{RF} + E_G)] \times V_{IN} \quad (EQ. 5)$$

Where:

E_{RG} = Tolerance of R_G

E_{RF} = Tolerance of R_F

E_G = Gain Error of the ISL28270

The term $[1 - (E_{RG} + E_{RF} + E_G)]$ is the deviation from the theoretical gain. Thus, $(E_{RG} + E_{RF} + E_G)$ is the total gain error. For example, if 1% resistors are used, the total gain error would be:

$$\text{TotalGainError} = \pm(E_{RG} + E_{RF} + E_G(\text{typical})) \quad (EQ. 6)$$

$$\text{TotalGainError} = \pm(0.01 + 0.01 + 0.005) = \pm 2.5\%$$

Disable/Power-Down

The ISL28270, ISL28273 and ISL28470 have an enable/disable pin for each channel. They can be powered down to reduce the supply current to typically 4µA when all channels are off. When disabled, the corresponding output is in a high impedance state. The active low \overline{EN} pin has an internal pull-down and hence can be left floating and the in-amp enabled by default. When the \overline{EN} is connected to an external logic, the in-amp will shutdown when the \overline{EN} pin is pulled above 2V, and will power up when \overline{EN} is pulled below 0.8V.

Unused Channels

The ISL28270, ISL28273 and ISL28470 are dual and quad channel op amps. If the application only requires one channel when using the ISL28270, ISL28273 or less than 4 channels when using the ISL28470, the user must configure the unused channel(s) to prevent them from oscillating. The unused channel(s) will oscillate if the input and output pins are floating. This will result in higher than expected supply currents and possible noise injection into the channel being used. The proper way to prevent this oscillation is to short the IN+ and IN- terminals to ground and short the FB+, FB- and the output terminals to ground as shown in Figure 52.

FIGURE 52. PREVENTING OSCILLATIONS IN UNUSED CHANNELS

Power Dissipation

It is possible to exceed the +150°C maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction temperature (T_{JMAX}) for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in the safe operating area. These parameters are related in Equation 7:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times P_{DMAXTOTAL}) \quad (EQ. 7)$$

where:

- $P_{DMAXTOTAL}$ is the sum of the maximum power dissipation of each amplifier in the package (P_{DMAX})
- P_{DMAX} for each amplifier can be calculated as shown in Equation 8:

$$P_{DMAX} = 2 \times V_S \times I_{SMAX} + (V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L} \quad (EQ. 8)$$

where:

- T_{MAX} = Maximum ambient temperature
- θ_{JA} = Thermal resistance of the package
- P_{DMAX} = Maximum power dissipation of 1 amplifier
- V_S = Supply voltage (Magnitude of V_+ and V_-)
- I_{MAX} = Maximum supply current of 1 amplifier
- V_{OUTMAX} = Maximum output voltage swing of the application
- R_L = Load resistance
