MAXIM

Precision Transimpedance Logarithmic Amplifier with Over 5 Decades of Dynamic Range

MAX4207

General Description

The MAX4207 logarithmic amplifier computes the log ratio of an input current relative to a reference current (externally or internally generated) and provides a corresponding voltage output with a default -0.25V/decade scale factor. The device operates from dual ±2.7V to ±5.5V supplies and is capable of measuring five decades of input current across a 10nA to 1mA range.

The MAX4207's uncommitted op amp can be used for a variety of functions, including filtering noise, adding offset, and adding additional gain. A 0.5V reference is also included to generate an optional precision current reference using an external resistor, which adjusts the log intercept of the MAX4207. The output-offset voltage and the adjustable scale factor are also set using external resistors.

The MAX4207 is available in a space-saving 16-pin thin QFN package (4mm x 4mm x 0.8mm), and is specified for operation over the -40°C to +85°C extended temperature range.

Applications

Photodiode Current Monitoring

Portable Instrumentation

Medical Instrumentation

Analog Signal Processing
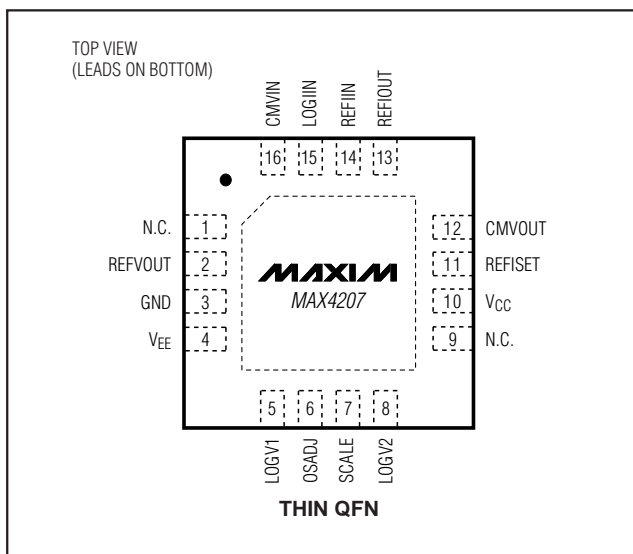

Features

♦ **±2.7V to ±5.5V Dual-Supply Operation**

♦ **5 Decades of Dynamic Range (10nA to 1mA)**

♦ **Monotonic Over a 1nA to 1mA Range**

♦ **-0.25V/Decade Internally Trimmed Output Scale Factor**

♦ **Adjustable Output Scale Factor**

♦ **Adjustable Output Offset Voltage**

♦ **Internal 10nA to 10µA Reference Current Source**

♦ **Input Amplifiers Summing Nodes at Ground**

♦ **Small 16-Pin Thin QFN Package (4mm x 4mm x 0.8mm)**

♦ **-40°C to +85°C Operating Temperature Range**

♦ **Evaluation Kit Available (Order MAX4206EVKIT)**

_____ *Pin Description*

| PIN	NAME	FUNCTION
1, 9	N.C.	No Connection. Not internally connected.
2	REFVOUT	1.238V Reference Voltage Output. Bypass REFVOUT to GND with a 0 to 1µF capacitor (optional).
3	GND	Ground
4	V_{EE}	Negative Power Supply. Bypass V_{EE} to GND with a 0.1µF capacitor.
5	LOGV1	Logarithmic Amplifier Voltage Output 1. The output scale factor of LOGV1 is -0.25V/decade.
6	OSADJ	Offset Adjust Input. Apply a voltage at OSADJ to adjust the LOGV2 output offset voltage (see the *Output Offset* section).
7	SCALE	Scale Factor Input. Adjust the output scale factor for LOGV2 using a resistive divider (see the *Scale Factor* section).
8	LOGV2	Logarithmic Amplifier Voltage Output 2. Adjust the output scale factor for LOGV2 using a resistive divider between SCALE, GND, and LOGV2 (see the *Scale Factor* section).
10	V_{CC}	Positive Power Supply. Bypass V_{CC} to GND with a 0.1µF capacitor.
11	REFISET	Current Reference Adjust Input. A resistor (R_{SET}), from REFISET to GND, adjusts the current at REFIOUT (see the *Adjusting the Logarithmic Intercept* section).
12	CMVOUT	0V Common-Mode Voltage Reference Output
13	REFIOUT	Current Reference Output. The internal current reference output is available at REFIOUT.
14	REFIIN	Current Reference Input. Apply an external reference current at REFIIN. I_{REFIIN} is the reference current used by the logarithmic amplifier when generating LOGV1.
15	LOGIIN	Current Input to Logarithmic Amplifier. LOGIIN is typically connected to a photodiode anode or other external current source.
16	CMVIN	Common-Mode Voltage Input. V_{CMVIN} is the common-mode voltage for the input and reference amplifiers (see the *Common Mode* section).
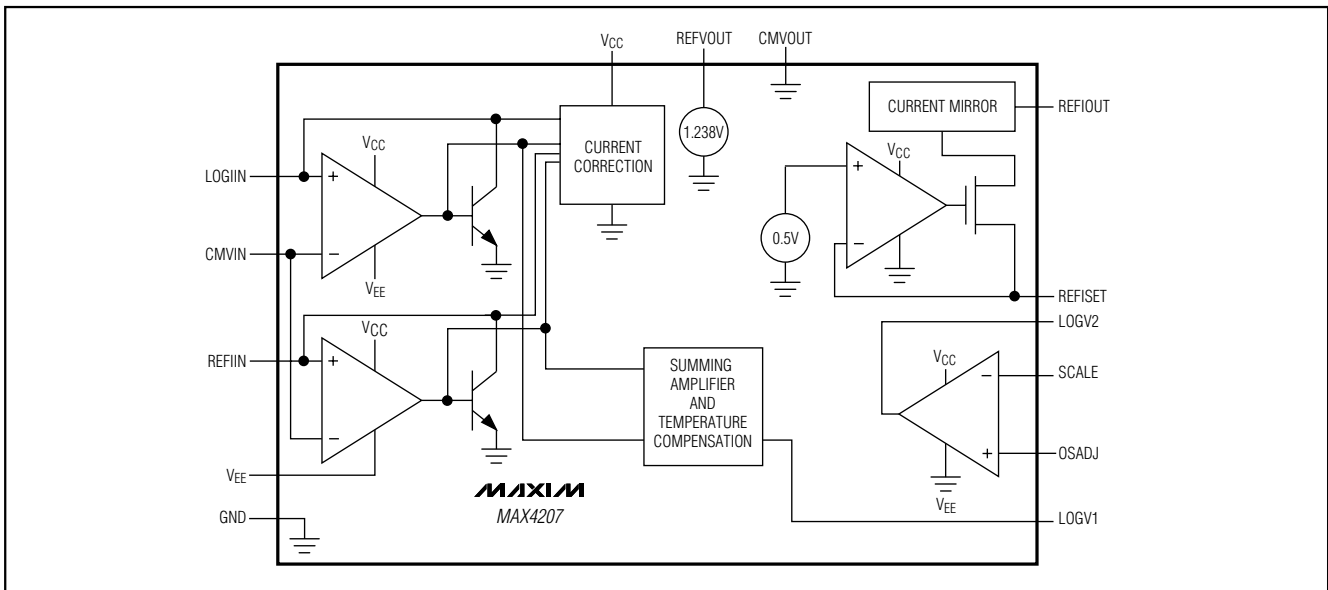

*Figure 1. Functional Diagram*

MAXIM

Figure 2. Simplified Model of a Logarithmic Amplifier

_____**Detailed Description**

Theory

Figure 2 shows a simplified model of a logarithmic amplifier. Two transistors convert the currents applied at LOGIIN and REFIIN to logarithmic voltages according to the following equation:

$$V_{BE} = \left(\frac{kT}{q}\right) \ln\left(\frac{I_C}{I_S}\right)$$

where:

   V_{BE} = base-emitter voltage of a bipolar transistor

   k = 1.381 x 10^{-23} J/K

   T = absolute temperature (K)

   q = 1.602 x 10^{-19} C

   I_C = collector current

   I_S = reverse saturation current

The logarithmic amplifier compares V_{BE1} to the reference voltage V_{BE2}, which is a logarithmic voltage for a known reference current, I_{REF}. The temperature dependencies of a logarithmic amplifier relate to the thermal voltage, (kT/q), and I_S. Matched transistors eliminate the I_S temperature dependence of the amplifier in the following manner:

$$V_{OUT} = V_{BE1} - V_{BE2}$$

$$= \left(\frac{kT}{q}\right) \ln\left[\left(\frac{I_{LOG}}{I_S}\right) - \left(\frac{kT}{q}\right) \ln\left(\frac{I_{REF}}{I_S}\right)\right]$$

$$= \left(\frac{kT}{q}\right)\left[\ln\left(\frac{I_{LOG}}{I_S}\right) - \ln\left(\frac{I_{REF}}{I_S}\right)\right]$$

$$= \left(\frac{kT}{q}\right)\left[\ln\left(\frac{I_{LOG}}{I_{REF}}\right)\right]$$

$$= \left(\frac{kT}{q}\right)\left(\ln(10)\right)\left[\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right)\right]$$

$$= K \times \log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right) \qquad \text{(see Figure 3)}$$

where:

k = scale factor (V/decade)

I_{LOG} = the input current at LOGIIN

I_{REF} = the reference current at REFIIN

The MAX4207 uses internal temperature compensation to virtually eliminate the effects of the thermal voltage, (kT/q), on the amplifier's scale factor, maintaining a constant slope over temperature.

Definitions

Transfer Function

The ideal logarithmic amplifier transfer function is:

$$V_{IDEAL} = K \times \log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right)$$

Adjust K (see the _Scale Factor_ section) to increase the transfer-function slope as illustrated in Figure 3. Adjust I_{REF} using REFISET (see the _Adjusting the Logarithmic Intercept_ section) to shift the logarithmic intercept to the left or right as illustrated in Figure 4.

Log Conformity

Log conformity is the maximum deviation of the MAX4207's output from the best-fit straight line of the V_{LOGV1} versus log (I_{LOG}/I_{REF}) curve. It is expressed as a percent of the full-scale output or an output voltage.

Referred-to-Input and Referred-to-Output Errors

The log nature of the MAX4207 insures that any additive error at LOGV1 corresponds to multiplicative error at the input, regardless of input level.

Precision Transimpedance Logarithmic Amplifier with Over 5 Decades of Dynamic Range

Figure 3. Ideal Transfer Function with Varying K

Figure 4. Ideal Transfer Function with Varying I$_{REF}$

Total Error

Total error (TE) is defined as the deviation of the output voltage, V$_{LOGV1}$, from the ideal transfer function (see the *Transfer Function* section):

$$V_{LOGV1} = V_{IDEAL} \pm TE$$

TE is a combination of the associated gain, input offset current, input bias current, output offset voltage, and transfer characteristic nonlinearity (log conformity) errors:

$$V_{LOGV2} = K(1 \pm \Delta K)\left[\log_{10}\left(\frac{I_{LOG} - I_{BIAS1}}{I_{REF} - I_{BIAS2}}\right) \pm 4\left(\pm V_{LC} \pm V_{OSOUT}\right)\right]$$

where V$_{LC}$ and V$_{OSOUT}$ are the log conformity and output offset voltages, respectively. Output offset is defined as the offset occurring at the output of the MAX4207 when equal currents are presented to I$_{LOG}$ and I$_{REF}$. Because the MAX4207 is configured with a gain of K = -0.25V/decade, a 4 should multiply the (±V$_{LC}$ ±V$_{OSOUT}$) term, if V$_{LC}$ and V$_{OSOUT}$ were derived from this default configuration.

I$_{BIAS1}$ and I$_{BIAS2}$ are currents in the order of 20pA, significantly smaller than I$_{LOG}$ and I$_{REF}$, and can therefore be eliminated:

$$V_{LOGV2} \cong K(1 \pm \Delta K)\left[\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right) \pm 4\left(\pm V_{LC} \pm V_{OSOUT}\right)\right]$$

Expanding this expression:

$$V_{LOGV2} \cong K\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right) \pm K\Delta K\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right)$$

$$\pm 4K(1 + \Delta K)\left(\pm V_{LC} \pm V_{OSOUT}\right)$$

The first term of this expression is the ideal component of V$_{LOGV1}$. The remainder of the expression is the TE:

$$TE \cong \pm K\Delta K\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right) \pm 4K(1 + \Delta K)\left(\pm V_{LC} \pm V_{OSOUT}\right)$$

In the second term, one can generally remove the products relating to ΔK, because ΔK is generally much less than 1. Hence, a good approximation for TE is given by:

$$TE \cong \pm K\left[\Delta K\log_{10}\left(\frac{I_{LOG}}{I_{REF}}\right) \pm 4\left(\pm V_{LC} \pm V_{OSOUT}\right)\right]$$

As an example, consider the following situation:

Full-scale input = 5V

I$_{LOG}$ = 100µA

I$_{REF}$ = 100nA

K = 1 ±5% V/decade (note that the uncommitted amplifier is configured for a gain of 4)

V$_{LC}$ = ±5mV (obtained from the *Electrical Characteristics* table)

V$_{OSOUT}$ = ±2mV (typ), and T$_A$ = +25°C.

MAXIM

Substituting into the TE approximation,

$$TE \cong \pm (1V/decade)(0.05 \log_{10} (100\mu A/100nA)$$
$$\pm 4 (\pm 5mV \pm 2mV) = \pm[0.15V \pm 4(\pm 7mV)]$$

As a worst case, one finds TE ≅ ±178mV or ±3.6% of full scale.

When expressed as a voltage, TE increases in proportion with an increase in gain as the contributing errors are defined at a specific gain. Calibration using a look-up table eliminates the effects of gain and output offset errors, leaving conformity error as the only factor contributing to total error. For further accuracy, consider temperature monitoring as part of the calibration process.

Applications Information

Input Current Range
Five decades of input current across a 10nA to 1mA range are acceptable for I_{LOG} and I_{REF}. The effects of bias currents increase as I_{LOG} and I_{REF} fall below 10nA. Bandwidth decreases at low I_{LOG} values (see the *Frequency Response and Noise Considerations* section). As I_{LOG} and I_{REF} increase to 1mA or higher, transistors become less logarithmic in nature. The MAX4207 incorporates leakage current compensation and high-current correction circuits to compensate for these errors.

Frequency Compensation
The MAX4207's frequency response is a function of the input current magnitude and the selected compensation network at LOGIIN and REFIIN. The compensation network comprised of C_{COMP} and R_{COMP} ensures stability over the specified range of input currents by introducing an additional pole/zero to the system. For the typical application, select C_{COMP} = 32pF and R_{COMP} = 330Ω.

Frequency Response and Noise Considerations
The MAX4207 bandwidth is proportional to the magnitude of the I_{REF} and I_{LOG} currents, whereas the noise is inversely proportional to I_{REF} and I_{LOG} currents.

Common Mode
A 0V common-mode input voltage, V_{CMVOUT}, is available at CMVOUT and can be used to bias the logging and reference amplifier inputs by connecting CMVOUT to CMVIN. A voltage between 0 and 0.5V, connected to CMVIN, may be used to bias the logging and reference transistor collectors, thereby optimizing performance.

Adjusting the Logarithmic Intercept
Adjust the logarithmic intercept by changing the reference current, I_{REF}. A resistor from REFISET to GND (see Figure 5) adjusts the reference current, according to the following equation:

$$R_{SET} = \frac{V_{REFISET}}{10 \times I_{REF}}$$

where $V_{REFISET}$ is 0.5V. Select R_{SET} between 5kΩ and 5MΩ. REFIOUT current range is 10nA to 10µA only.

Dual-Supply Operation
The MAX4207 operates only from dual ±2.7 to ±5.5V supplies. The relationship of inputs to outputs is a function of I_{REF}, relative to I_{LOG}, and the configuration of the uncommitted amplifier. The uncommitted amplifier can be configured in either inverting or noninverting mode. In an inverting configuration, the uncommitted amplifier output, LOGV2, is positive and LOGV1 is negative when I_{LOG} exceeds I_{REF}. When operating in a noninverting configuration, LOGV2 and LOGV1 are both negative when I_{LOG} exceeds I_{REF} (see Table 1). An inverting configuration of the uncommitted buffer is recommended when large output offset voltage adjustments are required using OSADJ. By connecting CMVOUT and CMVIN, the log and reference amplifier inputs (LOGIIN and REFIIN) are biased at 0V. Applying the external voltage (0 to 0.5V) to CMVIN optimizes the application's performance.

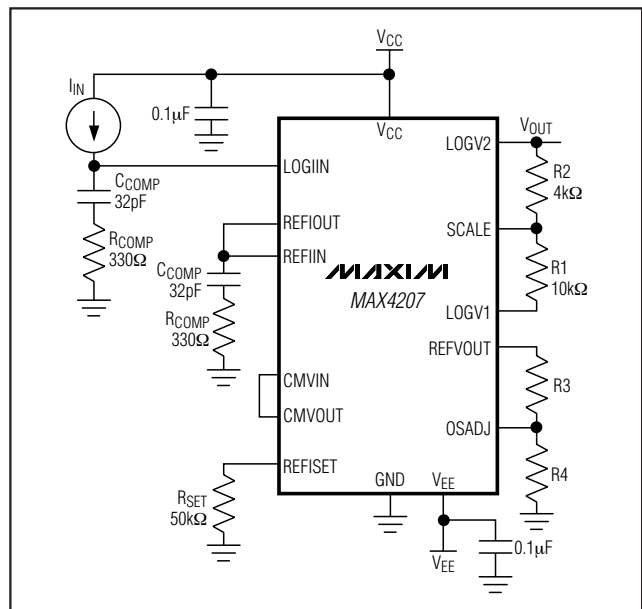

Figure 5. Typical Operating Circuit

MAX4207

Table 1. MAX4207 Example Configurations

LOGV2 AMPLIFIER CONFIGURATION	INPUT CONDITIONS	V_{LOGV1}	V_{LOGV2}
Inverting	$I_{LOG} > I_{REF}$ (constant)	Negative	Positive
	$I_{LOG} < I_{REF}$ (constant)	Positive	Negative
Noninverting	$I_{LOG} > I_{REF}$ (constant)	Negative	Negative
	$I_{LOG} < I_{REF}$ (constant)	Positive	Positive

Output Offset

The inverting configuration utilized by the MAX4207 facilitates large output-offset voltage adjustments. The magnitude of the offset voltage is given by the following equation:

$$V_{OS} = V_{OSADJ}\left(1 + \frac{R_2}{R_1}\right)$$

A resistive divider between REFVOUT, OSADJ, and GND can be used to adjust V_{OSADJ} (see Figure 5).

$$V_{OSADJ} = V_{REFOUT}\left(\frac{R_4}{R_3 + R_4}\right)$$

Scale Factor

The scale factor, K, is the slope of the logarithmic output. For the LOGV1 amplifier, K = -0.25V/decade. Adjust the overall scale factor for the MAX4207 using the uncommitted LOGV2 amplifier and the following equation, which refers to Figure 5:

$$R_2 = R_1 \left|\frac{K}{-0.25}\right|$$

Select R_2 between 1kΩ and 100kΩ.

Design Example

Desired:

Logarithmic intercept: 1µA

Overall scale factor = +1V/decade

$$R_{SET} = \frac{0.5V}{10 \times 1\mu A} = 50k\Omega$$

Select R_1 = 10kΩ:

$$R2 = 10k\Omega \times \left|\frac{1V/decade}{-0.25}\right| = 40k\Omega$$

Photodiode Current Monitoring

Figure 6 shows the MAX4207 in an optical-power measurement circuit, common in fiberoptic applications. The MAX4007 current monitor converts the sensed APD current to an output current that drives the MAX4207 LOGIIN input (APD current is scaled by 0.1). The MAX4007 also buffers the high-voltage APD voltages from the lower MAX4207 voltages. The MAX4207's internal current reference sources 10nA (R_{SET} = 5MΩ) to the REFIIN input. This configuration sets the logarithmic intercept to 10nA, corresponding to an APD current of 100nA. The unity-gain configuration of the output buffer maintains the -0.25V/decade gain present at the LOGV1 output.

Measuring Optical Absorbance

A photodiode provides a convenient means of measuring optical power, as diode current is proportional to the incident optical power. Measure absolute optical power using a single photodiode connected at LOGIIN, with the MAX4207's internal current reference driving REFIIN. Alternatively, connect a photodiode to each of the MAX4207's logging inputs, LOGIIN and REFIIN, to measure relative optical power (Figure 7).

In absorbance measurement instrumentation, a reference light source is split into two paths. The unfiltered path is incident upon the photodiode of the reference channel, REFIIN. The other path passes through a sample of interest, with the resulting filtered light incident on the photodiode of the second channel, LOGIIN. The MAX4207 outputs provide voltages proportional to the log ratio of the two optical powers—an indicator of the optical absorbance of the sample.

In wavelength-locking applications, often found in fiberoptic communication modules, two photodiode currents provide a means of determining whether a given optical channel is tuned to the desired optical frequency. In this application, two bandpass optical filters with overlapping "skirts" precede each photodiode. With proper filter selection, the MAX4207 output can vary monotonically (ideally linearly) with optical frequency.

Capacitive Loads

The MAX4207 drives capacitive loads of up to 50pF. Reactive loads decrease phase margin and can produce excessive ringing and oscillation. Use an isolation resistor in series with LOGV1 or LOGV2 to reduce the effect of large capacitive loads. Recall that the combination of the capacitive load and the small isolation resistor limits AC performance.

Power Dissipation

The LOGV1 and LOGV2 amplifiers are capable of sourcing or sinking in excess of 30mA. Ensure that the continuous power dissipation rating for the MAX4207 is not exceeded.

TQFN Package

The 16-lead thin QFN package has an exposed paddle that provides a heat-removal path, as well as excellent electrical grounding to the PC board. The MAX4207's exposed pad is internally connected to V_{EE}, and can either be connected to the PC board V_{EE} plane or left unconnected. Ensure that only V_{EE} traces are routed under the exposed paddle.

Precision Transimpedance Logarithmic Amplifier with Over 5 Decades of Dynamic Range

Layout and Bypassing

Bypass V_{CC} and V_{EE} to GND with ceramic 0.1µF capacitors. Place the capacitors as close to the device as possible. Bypass REFVOUT and/or CMVOUT to GND with a 0.1µF ceramic capacitor for increased noise immunity and a clean reference current. For low-current operation, it is recommended to use metal guard rings around LOGIIN, REFIIN, and REFISET. Connect this guard ring to CMVOUT.

## Chip Information

TRANSISTOR COUNT: 754

PROCESS: BiCMOS

NOTES:
1. DIMENSIONING & TOLERANCING CONFORM TO ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS. ANGLES ARE IN DEGREES.
3. N IS THE TOTAL NUMBER OF TERMINALS.
4. THE TERMINAL #1 IDENTIFIER AND TERMINAL NUMBERING CONVENTION SHALL CONFORM TO JESD 95-1 SPP-012. DETAILS OF TERMINAL #1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE TERMINAL #1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE.
5. DIMENSION b APPLIES TO METALLIZED TERMINAL AND IS MEASURED BETWEEN 0.25 mm AND 0.30 mm FROM TERMINAL TIP.
6. ND AND NE REFER TO THE NUMBER OF TERMINALS ON EACH D AND E SIDE RESPECTIVELY.
7. DEPOPULATION IS POSSIBLE IN A SYMMETRICAL FASHION.
8. COPLANARITY APPLIES TO THE EXPOSED HEAT SINK SLUG AS WELL AS THE TERMINALS.
9. DRAWING CONFORMS TO JEDEC MO220, EXCEPT FOR T2444-1, T2444-3 AND T2444-4.
