
#### Abstract

General Description The MAX4188/MAX4189/MAX4190 are low-power, current-feedback video amplifiers featuring fast disable/enable times and low switching transients. The triple MAX4188 and the single MAX4190 are optimized for applications with closed-loop gains of $+2 \mathrm{~V} / \mathrm{V}(6 \mathrm{~dB})$ or greater and provide a -3 dB bandwidth of 200 MHz and 185 MHz , respectively. The triple MAX4189 is optimized for closed-loop applications with gains of $+1 \mathrm{~V} / \mathrm{V}$ (0dB) or greater and provides a $250 \mathrm{MHz}-3 \mathrm{~dB}$ bandwidth. These amplifiers feature 0.1 dB gain flatness up to 80 MHz with differential gain and phase errors of $0.03 \%$ and $0.05^{\circ}$. These features make the MAX4188 family ideal for video applications. The MAX4188/MAX4189/MAX4190 operate from a +5 V single supply or from $\pm 2.25 \mathrm{~V}$ to $\pm 5.5 \mathrm{~V}$ dual supplies. These amplifiers consume only 1.5 mA per amplifier and are capable of delivering $\pm 55 \mathrm{~mA}$ of output current, making them ideal for portable and battery-powered equipment. The MAX4188/MAX4189/MAX4190 have a high-speed disable/enable mode that isolates the inputs, places the outputs in a high-impedance state, and reduces the supply current to $450 \mu \mathrm{~A}$ per amplifier. Each amplifier can be disabled independently. High off isolation, low switching transient, and fast enable/disable times (120ns/35ns) allow these amplifiers to be used in a wide range of multiplexer applications. A settling time of 22 ns to $0.1 \%$, a slew rate of up to $350 \mathrm{~V} / \mu \mathrm{s}$, and low distortion make these devices useful in many generalpurpose, high-speed applications. The MAX4188/MAX4189 are available in a tiny 16-pin QSOP package, and the MAX4190 is available in a space-saving 8-pin $\mu \mathrm{MAX}{ }^{\circledR}$ package.

## Applications

High-Definition Surveillance Video
High-Speed Switching/Multiplexing
Portable/Battery-Powered Video/Multimedia Systems
High-Speed Analog-to-Digital Buffers
Medical Imaging
High-Speed Signal Processing
Professional Cameras
CCD Imaging Systems
RGB Distribution Amplifiers
Pin Configuration appears at end of data sheet.
$\mu M A X$ is a registered trademark of Maxim Integrated Products, Inc.

- Low Supply Current: 1.5mA per Amplifier
- Fast Enable/Disable Times: 120ns/35ns
- Very Low Switching Transient: 45mVp-p
- High Speed

200MHz -3dB Small-Signal Bandwidth
(MAX4188, AvcL $\geq+2$ )
250MHz -3dB Small-Signal Bandwidth
(MAX4189, AvcL $\geq+1$ )
185MHz -3dB Small-Signal Bandwidth
(MAX4190, Avcl $\geq+2$ )

- High Slew Rate

350V/ $\mu \mathrm{s}$ (MAX4188, AvcL $\geq+2$ )
175V/ $\mu \mathrm{s}$ (MAX4189, AvcL $\geq+1$ )

- Excellent Video Specifications
$85 \mathrm{MHz}-0.1 \mathrm{~dB}$ Gain Flatness (MAX4190)
$30 \mathrm{MHz}-0.1 \mathrm{~dB}$ Gain Flatness (MAX4189)
Differential Gain/Phase Errors
0.03\%/0.05 ${ }^{\circ}$ (MAX4188)
- Low-Power Disable Mode

Inputs Isolated, Outputs Placed in High-Z
Supply Current Reduced to $450 \mu \mathrm{~A}$ per Amplifier

- Fast Settling Time of 22ns to 0.1\%
- Low Distortion

70 dB SFDR ( $\mathrm{f}_{\mathrm{c}}=5 \mathrm{MHz}, \mathrm{V}_{\mathrm{O}}=2 \mathrm{~V}_{\mathrm{p}-\mathrm{p}}$, MAX4188)

- Available in Space-Saving Packages 16-Pin QSOP (MAX4188/MAX4189) 8-Pin $\mu$ MAX (MAX4190)

## Single/Triple, Low-Glitch, 250MHz, CurrentFeedback Amplifiers with High-Speed Disable

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$ )
IN_+, IN_-, DISABLE_ Voltage .........(VEE - 0.3V) to (VCC + 0.3V)
Differential Input Voltage (IN_+ to IN_-).............................. $\pm 1.5 \mathrm{~V}$
Maximum Current into IN_+ or IN_-.................................. $\pm 10 \mathrm{~mA}$
Output Short-Circuit Current Duration.........................Continuous
Continuous Power Dissipation $\left(\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}\right)$
8 -Pin SO (derate $5.88 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ).
471 mW
8-Pin $\mu$ MAX (derate $4.1 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## DC ELECTRICAL CHARACTERISTICS—Dual Supplies

## Detailed Description

The MAX4188/MAX4189/MAX4190 are very low-power, current-feedback amplifiers featuring bandwidths up to $250 \mathrm{MHz}, 0.1 \mathrm{~dB}$ gain flatness to 80 MHz , and low differential gain $(0.03 \%)$ and phase $\left(0.05^{\circ}\right)$ errors. These amplifiers achieve very high bandwidth-to-power ratios while maintaining low distortion, wide signal swing, and excellent load-driving capabilities. They are optimized for $\pm 5 \mathrm{~V}$ supplies but are also fully specified for single +5 V operation. Consuming only 1.5 mA per amplifier, these devices have $\pm 55 \mathrm{~mA}$ output current drive capability and achieve low distortion even while driving $150 \Omega$ loads.

Wide bandwidth, low power, low differential phase/gain error, and excellent gain flatness make the MAX4188 family ideal for use in portable video equipment such as video cameras, video switchers, and other batterypowered equipment. Their two-stage design provides higher gain and lower distortion than conventional sin-gle-stage, current-feedback amplifiers. This feature, combined with a fast settling time, makes these devices suitable for buffering high-speed analog-to-digital converters.
The MAX4188/MAX4189/MAX4190 have a high-speed, low-power disable mode that is activated by driving the amplifiers' DISABLE input low. In the disable mode, the

## Single/Triple, Low-Glitch, 250MHz, CurrentFeedback Amplifiers with High-Speed Disable

amplifiers achieve very high isolation from input to output ( 65 dB at 10 MHz ), and the outputs are placed into a highimpedance state. These amplifiers achieve low switch-ing-transient glitches (<45mVP-P) when switching between enable and disable modes. Fast enable/disable times ( $120 \mathrm{~ns} / 35 \mathrm{~ns}$ ), along with high off-isolation and low switching transients, allow these devices to be used as high-performance, high-speed multiplexers. This is achieved by connecting the outputs of multiple amplifiers together and controlling the DISABLE inputs to enable one amplifier and disable all others. The disabled amplifiers present a very light load ( $1 \mu \mathrm{~A}$ leakage current and 3.5 pF capacitance) to the active amplifier's output. The feedback network impedance of all the disabled amplifiers must still be considered when calculating the total load on the active amplifier output. Figure 1 shows an application circuit using the MAX4188 as a $3: 1$ video multiplexer.
The DISABLE_ logic threshold is typically $\mathrm{V}_{\mathrm{CC}}-2.5 \mathrm{~V}$, independent of $\mathrm{V}_{\mathrm{EE}}$. For a single +5 V supply or dual $\pm 5 \mathrm{~V}$ supplies, the disable inputs are CMOS-logic compatible. The amplifiers default to the enabled mode if the DISABLE pin is left unconnected. If the DISABLE pin is left floating, take proper care to ensure that no high-frequency signals are coupled to this pin, as this may cause false triggering.

## Applications Information

## Theory of Operation

The MAX4188/MAX4189/MAX4190 are current-feedback amplifiers, and their open-loop transfer function is expressed as a transimpedance, $\Delta \mathrm{V}$ OUT/ $/ \Delta I \mathrm{I}$, or Tz . The frequency behavior of the open-loop transimpedance is similar to the open-loop gain of a voltage-mode feedback amplifier. That is, it has a large DC value and decreases at approximately 6 dB per octave.
Analyzing the follower with gain, as shown in Figure 2, yields the following transfer function:

Vout / VIN $=\mathrm{G} \times[(\mathrm{Tz}(\mathrm{S}) / \mathrm{Tz}(\mathrm{s})+\mathrm{G} \times(\mathrm{RIN}+\mathrm{RF})]$
where $G=A v C L=1+(R F / R G)$, and $R I N=1 / g m \cong$ $300 \Omega$.
At low gains, $G \times \operatorname{RiN}<R F$. Therefore, the closed-loop bandwidth is essentially independent of closed-loop gain. Similarly $T_{Z}>R_{F}$ at low frequencies, so that:

$$
\frac{V_{\text {OUT }}}{V_{\text {IN }}}=G=1+\left(R_{F} / R_{G}\right)
$$

## Layout and Power－Supply Bypassing

As with all wideband amplifiers，a carefully laid out PCB and adequate power－supply bypassing are essential to realizing the optimum AC performance of MAX4188／ MAX4189／MAX4190．The PC board should have at least two layers．Signal and power should be on one layer．A large low－impedance ground plane，as free of voids as possible，should be the other layer．With multi－ layer boards，locate the ground plane on a layer that incorporates no signal or power traces．

Do not use wire－wrap boards or breadboards and sockets．Wire－wrap boards are too inductive． Breadboards and sockets are too capacitive．Surface－ mount components have lower parasitic inductance and capacitance，and are therefore preferable to through－hole components．Keep lines as short as pos－ sible to minimize parasitic inductance，and avoid $90^{\circ}$ turns．Round all corners．Terminate all unused amplifier inputs to ground with a $100 \Omega$ or $150 \Omega$ resistor．

The MAX4188／MAX4189／MAX4190 achieve a high degree of off－isolation（ 65 dB at 10 MHz ）and low crosstalk（ -55 dB at 10 MHz ）．The input and output sig－ nal traces must be kept from overlapping to achieve high off－isolation．Coupling between the signal traces of different channels will degrade crosstalk．The signal traces of each channel should be kept from overlap－ ping with the signal traces of the other channels．

Figure 3a．Inverting Gain Configuration

Adequate bypass capacitance at each supply is very important to optimize the high－frequency performance of these amplifiers．Inadequate bypassing will also degrade crosstalk rejection，especially with heavier loads．Use a $1 \mu \mathrm{~F}$ capacitor in parallel with a $0.01 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$ capacitor between each supply pin and ground to achieve optimum performance．The bypass capacitors should be located as close to the device as possible．A $10 \mu \mathrm{~F}$ low－ESR tantalum capacitor may be required to produce the best settling time and lowest distortion when large transient currents must be delivered to a load．

Choosing Feedback and Gain Resistors The optimum value of the external－feedback（RF）and gain－setting（ $\mathrm{R}_{\mathrm{G}}$ ）resistors used with the MAX4188／ MAX4189／MAX4190 depends on the closed－loop gain and the application circuit＇s load．Table 1 lists the opti－ mum resistor values for some specific gain configura－ tions．One－percent resistor values are preferred to maintain consistency over a wide range of production lots．Figures 3a and 3b show the standard inverting and noninverting configurations．Note that the nonin－ verting circuit gain（Figure 3b）is 1 plus the magnitude of the inverting closed－loop gain．Otherwise，the two circuits are identical．

DC and Noise Errors
Several major error sources must be considered in any op amp. These apply equally to the MAX4188/ MAX4189/MAX4190. Offset-error terms are given by the equation below. Voltage and current-noise errors are root-square summed and are therefore computed separately. In Figure 4, the total output offset voltage is determined by the following factors:

- The input offset voltage (VOS) times the closed-loop gain ( $1=R_{F} / R_{G}$ ).
- The positive input bias current ( $\mathrm{I}_{+}$) times the source resistor (RS) (usually $50 \Omega$ or $75 \Omega$ ), plus the negative input bias current (IB-) times the parallel combination of $R_{G}$ and $R_{F}$. In current-feedback amplifiers, the input bias currents at the $\mathrm{IN}+$ and IN terminals do not track each other and may have opposite polarity, so there is no benefit to matching the resistance at both inputs.

The equation for the total DC error at the output is:

$$
V_{\text {OUT }}=\left[\left(l_{B+}\right) R_{S}+\left(l_{B-}\right)\left(R_{F} \| R_{G}\right)+V_{O S}\right]\left(1+\frac{R_{F}}{R_{G}}\right)
$$

Figure 4. Output Offset Voltage

## Single/Triple, Low-Glitch, 250MHz, CurrentFeedback Amplifiers with High-Speed Disable

The total output-referred noise voltage is:

$$
\begin{aligned}
& e_{n(\text { OUT })}=\left(1+\frac{R_{F}}{R_{G}}\right) x \\
& \sqrt{\left[\left(i_{n+}\right) R_{S}\right]^{2}+\left[\left(i_{n-}\right) R_{F} \| R_{G}\right]^{2}+\left(e_{n}\right)^{2}}
\end{aligned}
$$

The MAX4188/MAX4189/MAX4190 have a very low, $2 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ noise voltage. The current noise at the positive input ( $\mathrm{in}_{+}$) is $4 \mathrm{pA} / \sqrt{\mathrm{Hz}}$, and the current noise at the inverting input is $5 \mathrm{pA} / \sqrt{\mathrm{Hz}}$.
An example of the DC error calculations, using the MAX4188 typical data and typical operating circuit where $R_{F}=R_{G}=560 k \Omega\left(R_{F} \| R_{G}=280 \Omega\right)$, and $R S=37.5 \Omega$, gives the following:
$V_{\text {OUT }}=\left[\begin{array}{l}\left(\begin{array}{l}\left.1 \times 10^{-6}\right) \times 37.5+\left(2 \times 10^{-6}\right) 280 \\ +1.5 \times 10^{-3}\end{array}\right] \times(1+1)\end{array}\right.$
$V_{\text {OUT }}=4.1 \mathrm{mV}$
Calculating the total output noise in a similar manner yields:

$$
\begin{aligned}
& e_{n(\text { OUT })}=(1+1) \sqrt{\left(4 \times 10^{-12} \times 37.5\right)^{2}+} \\
& e_{n(O U T)}=4.8 \mathrm{nV} / \sqrt{\mathrm{Hz}}
\end{aligned}
$$

Figure 5. Video Line Driver Application

With a 200MHz system bandwidth, this calculates to $68 \mu \mathrm{~V}_{\mathrm{RMS}}$ (approximately $408 \mu \mathrm{VP}-\mathrm{P}$, choosing the sixsigma value).

Video Line Driver
The MAX4188/MAX4189/MAX4190 are well suited to drive coaxial transmission lines when the cable is terminated at both ends (Figure 5). Cable frequency response can cause variations in the signal's flatness. See Table 1 for optimum RF and RG values.

## Driving Capacitive Loads

The MAX4188/MAX4189/MAX4190 are optimized for AC performance. Reactive loads decrease phase margin and may produce excessive ringing and oscillation. Unlike most high-speed amplifiers, the MAX4188/ MAX4189/MAX4190 are tolerant of capacitive loads up to 50 pF . Capacitive loads greater than 50 pF may cause ringing and oscillation. Figure 6a shows a circuit that eliminates this problem. Placing the small (usually $15 \Omega$ to $33 \Omega$ ) isolation resistor, RS, before the reactive load prevents ringing and oscillation. At higher capacitive loads, the interaction of the load capacitance and isolation resistor controls AC performance. Figures 6b and 6 c show the MAX4188 and MAX4189 frequency response with a 100pF capacitive load. Note that in each case, gain peaking is substantially reduced when the $20 \Omega$ resistor is used to isolate the capacitive load from the amplifier output.
