- \bullet **Pressure Sensors**
- \bullet **Test and Measurement**

DESCRIPTION

The ADS1271 is a 24-bit, delta-sigma analog-to-digital converter (ADC) with a data rate up to 105kSPS. It offers a unique combination of excellent DC accuracy and outstanding AC performance. The high-order, chopper-stabilized modulator achieves very low drift with low in-band noise. The onboard decimation filter suppresses modulator and signal out-of-band noise. The ADS1271 provides a usable signal bandwidth up to 90% of the Nyquist rate with less than 0.005dB of ripple.

Traditionally, industrial delta-sigma ADCs offering good drift performance use digital filters with large passband droop. As a result, they have limited signal bandwidth and are mostly suited for DC measurements. High-resolution ADCs in audio applications offer larger usable bandwidths, but the offset and drift specification are significantly weaker than their industrial counterparts. The ADS1271 combines these converters, allowing high-precision industrial measurement with excellent DC and AC specifications ensured over an extended industrial temperature range.

Three operating modes allow for optimization of speed, resolution, and power. A selectable SPI or a frame-sync serial interface provides for convenient interfacing to microcontrollers or DSPs. The output from the modulator is accessible for external digital filter applications. All operations, including internal offset calibration, are controlled directly by pins; there are no registers to program.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments ÆÑ semiconductor products and disclaimers thereto appears at the end of this data sheet.

SPI is a trademark of Motorola Inc. All other trademarks are the property of their respective owners.

PRODUCTION DATA information is current as of publication date. Products
conform to specifications per the terms of TexasInstements standard warranty.
Production processing does not necessarily include testing of all parame

ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range unless otherwise noted(1)

(1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ORDERING INFORMATION

For the most current package and ordering information, see the Package Option Addendum located at the end of this data sheet, or refer to our web site at www.ti.com.

ELECTRICAL CHARACTERISTICS

All specifications at $T_A = -40^{\circ}$ C to +105°C, AVDD = +5V, DVDD = +1.8V, f_{CLK} = 27MHz, VREFP = 2.5V, and VREFN = 0V, unless otherwise noted.

Specified values for ADS1271 and ADS1271B (high-grade version) are the same, except where shown in **BOLDFACE** type.

(1) FSR = full-scale range = $2V_{REF}$.
(2) Minimum SNR is ensured by the limit of the DC noise specification.

(3) THD includes the first nine harmonics of the input signal.

(4) MODE and FORMAT pins excluded.

(5) See the text for more details on SCLK.

ELECTRICAL CHARACTERISTICS (continued)

All specifications at $T_A = -40^\circ \text{C}$ to +105°C, AVDD = +5V, DVDD = +1.8V, f_{CLK} = 27MHz, VREFP = 2.5V, and VREFN = 0V, unless otherwise noted.

Specified values for ADS1271 and ADS1271B (high-grade version) are the same, except where shown in **BOLDFACE** type.

(1) FSR = full-scale range = $2V_{REF}$.
(2) Minimum SNR is ensured by the limit of the DC noise specification.

(3) THD includes the first nine harmonics of the input signal.

(4) MODE and FORMAT pins excluded.

(5) See the text for more details on SCLK.

TIMING CHARACTERISTICS: SPI FORMAT

TIMING REQUIREMENTS: SPI FORMAT

For $T_A = -40^{\circ}$ C to +105°C and DVDD = 1.65V to 3.6V.

 (1) Load on \overline{DRDY} and $DOUT = 20pF$.

 (2) For best performance, limit $f_{\text{SCLK}}/f_{\text{CLK}}$ to ratios of 1, 1/2, 1/4, 1/8, etc.

(3) t_{DOHD} (DOUT hold time) and t_{DIHD} (DIN Hold time) are specified under opposite worst case conditions (digital supply voltage and ambient temperature). Under equal conditions, with DOUT connected directly to DIN, the timing margin is 4nS.

TIMING CHARACTERISTICS: FRAME-SYNC FORMAT

TIMING REQUIREMENTS: FRAME-SYNC FORMAT

for $T_A = -40^{\circ}$ C to +105°C and DVDD = 1.65V to 3.6V.

(1) The ADS1271 automatically detects either frame period (only 256 or 512 allowed).

 (2) Load on DOUT = 20pF.

(3) t_{DOHD} (DOUT hold time) and t_{DIHD} (DIN Hold time) are specified under opposite worst case conditions (digital supply voltage and ambient temperature). Under equal conditions, with DOUT connected directly to DIN, the timing margin is 4nS.

TYPICAL CHARACTERISTICS (continued)

OVERVIEW

The ADS1271 is a 24-bit, delta-sigma ADC. It offers the combination of outstanding DC accuracy and superior AC performance. Figure 43 shows the block diagram for the ADS1271. The ADS1271 converter is comprised of an advanced, 6th-order, chopper-stabilized, delta-sigma modulator followed by a low-ripple, linear phase FIR filter. The modulator measures the differential input signal, V_{IN} = (AINP – AINN), against the differential reference, V_{RFF} = (VREFP – VREFN). The digital filter receives the modulator signal and provides a low-noise digital output. To allow tradeoffs among speed, resolution, and power, three modes of operation are supported on the ADS1271: High-Speed, High-Resolution, and Low-Power. Table 1 summarizes the performance of each mode.

In High-Speed mode, the data rate is 105kSPS; in High-Resolution mode, the SNR = 109dB; and in Low-Power mode, the power dissipation is only 35mW. The digital filter can be bypassed, enabling direct access to the modulator output.

The ADS1271 is configured by simply setting the appropriate IO pins—there are no registers to program. Data is retrieved over a serial interface that supports both SPI and Frame-Sync formats. The ADS1271 has a daisy-chainable output and the ability to synchronize externally, so it can be used conveniently in multichannel systems.

Figure 43. Block Diagram

Table 1. Operating Mode Performance Summary

ANALOG INPUTS (AINP, AINN)

The ADS1271 measures the differential input signal V_{1N} = (AINP – AINN) against the differential reference $V_{REF} = (VREF - VREFN)$. The most positive measurable differential input is $+V_{RFF}$, which produces the most positive digital output code of 7FFFFFh. Likewise, the most negative measurable differential input is - VREF, which produces the most negative digital output code of 800000h.

While the ADS1271 measures the differential input signal, the absolute input voltage is also important. This is the voltage on either input (AINP or AINN) with respect to AGND. The range for this voltage is:

−0.1V < (AINN or AINP) < AVDD +0.1V

If either input is taken below $-0.4V$ or above (AVDD + 0.4), ESD protection diodes on the inputs may turn on.

If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe values (see Absolute Maximum Ratings).

The ADS1271 uses switched-capacitor circuitry to measure the input voltage. Internal capacitors are charged by the inputs and then discharged. Figure 44 shows a conceptual diagram of these circuits. Switch S2 represents the net effect of the modulator circuitry in discharging the sampling capacitor; the actual implementation is different. The timing for switches S1 and S2 is shown in Figure 45. The sampling time $(t_{SAMP}F)$ is the inverse of modulator sampling frequency (f_{MOD}) and is a function of the mode, format, and frequency of CLK, as shown in Table 2. When using the Frame-Sync format with High-Resolution or Low-Power modes, the ratio between f_{MOD} and $f_{\text{CI K}}$ depends on the frame period that is set by the FSYNC input.

Figure 44. Equivalent Analog Input Circuitry

Figure 45. S1 and S2 Switch Timing for Figure 44

The average load presented by the switched capacitor input can be modeled with an effective differential impedance, as shown in Figure 46. Note that the effective impedance is a function of f_{MOD} .

Figure 46. Effective Input Impedances

The ADS1271 is a very high-performance ADC. For optimum performance, it is critical that the appropriate circuitry be used to drive the ADS1271 inputs. See the Application Information section for the recommended circuits.

VOLTAGE REFERENCE INPUTS (VREFP, VREFN)

The voltage reference for the ADS1271 ADC is the differential voltage between VREFP and VREFN: V_{RFF} = (VREFP–VREFN). The reference inputs use a structure similar to that of the analog inputs with the equivalent circuitry on the reference inputs shown in Figure 47. As with the analog inputs, the load presented by the switched capacitor can be modeled with an effective impedance, as shown in Figure 48.

Figure 47. Equivalent Reference Input Circuitry

Figure 48. Effective Reference Impedance

ESD diodes protect the reference inputs. To keep these diodes from turning on, make sure the voltages on the reference pins do not go below AGND by more than 0.4V, and likewise do not exceed AVDD by 0.4V. If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe values (see Absolute Maximum Ratings).

Note that the valid operating range of the reference inputs is limited to the following:

For the ADS1271:

−0.1V ≤ VREFN ≤ VREFP − 2V

VREFN + 2V ≤ VREFP ≤ AVDD − 0.5V

For the ADS1271B:

−0.1V ≤ VREFN ≤ VREFP − 0.5V

 $VREFN + 0.5V \leq VREFP \leq AVDD + 0.1V$

A high-quality reference voltage with the appropriate drive strength is essential for achieving the best performance from the ADS1271. Noise and drift on the reference degrade overall system performance. See the Application Information section for example reference circuits.

CLOCK INPUT (CLK)

The ADS1271 requires an external clock signal to be applied to the CLK input pin. As with any high-speed data converter, a high-quality, low-jitter clock is essential for optimum performance. Crystal clock oscillators are the recommended clock source. Make sure to avoid excess ringing on the clock input; keeping the clock trace as short as possible using a 50 Ω series resistor will help.

The ratio between the clock frequency and output data rate is a function of the mode and format. Table 3 shows the ratios when the SPI format is selected. Also included in this table is the typical CLK frequency and the corresponding

data rate. When High-Speed mode is used, each conversion takes 256 CLK periods. When High-Resolution or Low-Power modes are selected, the conversions take 512 CLK periods.

Table 4 shows the ratios when the Frame-Sync format is selected. When using the Frame-Sync format in either High-Resolution or Low-Power mode, the f_{CLK}/f_{DATA} ratio can be 256 or 512. The ADS1271 automatically detects which ratio is being used. Using a ratio of 256 allows the CLK frequency to be reduced by a factor of two while maintaining the same data rate. The output data rate scales with the clock frequency. See the Serial Interface section for more details on the Frame-Sync operation.

Table 3. Clock Ratios for SPI Format

Table 4. Clock Ratios for Frame-Sync Format

MODE SELECTION (MODE)

The ADS1271 supports three modes of operation: High-Speed, High-Resolution, and Low-Power. The mode selection is determined by the status of the digital input MODE pin, as shown in Table 5. A high impedance, or floating, condition allows the MODE pin to support a third state. The ADS1271 constantly monitors the status of the MODE pin during operation and responds to a change in status after 12,288 CLK periods. When floating the MODE pin, keep the total capacitance on the pin less than 100pF and the resistive loading greater than 10M Ω to ensure proper operation. Changing the mode clears the internal offset calibration value. If onboard offset calibration is being used, be sure to recalibrate after a mode change.

When daisy-chaining multiple ADS1271s together and operating in High-Resolution mode (MODE pin floating), the MODE pin of each device must be isolated from one another; this ensures proper device operation. The MODE pins can be tied together for High-Speed and Low-Power modes.

Table 5. Mode Selection

(1) Load on MODE: $C < 100pF$, R $> 10M\Omega$.

When using the SPI format, DRDY is held high after a mode change occurs until settled (or valid) data is ready, as shown in Figure 49.

In Frame-Sync format, the DOUT pin is held low after a mode change occurs until settled data is ready, as shown in Figure 49. Data can be read from the device to detect when DOUT changes to logic 1, indicating valid data.

FORMAT SELECTION (FORMAT)

To help connect easily to either microcontrollers or DSPs, the ADS1271 supports two formats for the serial interface: an SPI-compatible interface and a Frame-Sync interface. The format is selected by the FORMAT pin, as shown in Table 6. If the status of this pin changes, perform a sync operation afterwards to ensure proper operation. The modulator output mode does not require a sync operation.

Table 6. Format Selection

(1) Load on FORMAT: $C < 100pF$, R > 10M Ω .

(2) See Modulator Output section.

Figure 49. Mode Change Timing

SYNCHRONIZATION

The SYNC/PDWN pin has two functions. When pulsed, it synchronizes the start of conversions and, if held low for more than 2^{19} CLK cycles (t_{SYN}), places the ADS1271 in Power-Down mode. The SYNC/PDWN pin can be left high for continuous data acquisition. See the Power-Down and Offset Calibration section for more details.

The ADS1271 can be synchronized by pulsing the SYNC/PDWN pin low and then returning the pin high. When the pin goes low, the conversion process is stopped, and the internal counters used by the digital filter are reset. When the SYNC/PDWN pin is returned high, the conversion process is restarted. Synchronization allows the conversion to be aligned with an external event; for example, the changing of an external multiplexer on the analog inputs, or by a reference timing pulse.

The SYNC/PDWN pin is capable of synchronizing multiple ADS1271s to within the same CLK cycle. Figure 50 shows the timing requirement of SYNC/PDWN and CLK in SPI format.

Figure 51 shows the timing requirement for Frame-Sync format.

www.ti.com

FRUMENTS

After synchronization, indication of valid data depends on the whether SPI or Frame-Sync format was used.

In the SPI format, DRDY goes high as soon as SYNC/PDWN is taken low, as shown in Figure 50. After SYNC/PDWN is returned high, DRDY stays high while the digital filter is settling. Once valid data is ready for retrieval, DRDY goes low.

In the Frame-Sync format, DOUT goes low as soon as SYNC/PDWN is taken low, as shown in Figure 51. After SYNC/PDWN is returned high, DOUT stays low while the digital filter is settling. Once valid data is ready for retrieval, DOUT begins to output valid data. For proper synchronization, FSYNC, SCLK, and CLK must be established before taking **SYNC/PDWN** high, and must then remain running.

Figure 50. Synchronization Timing for SPI format

Figure 51. Synchronization Timing for Frame-Sync Format

POWER-DOWN AND OFFSET CALIBRATION

In addition to controlling synchronization, the SYNC/PDWN pin also serves as the control for Power-Down mode and offset calibration. To enter this mode, hold the SYNC/PDWN pin low for at least 2¹⁹ CLK periods. While in Power-Down mode, both the analog and digital circuitry are completely deactivated. The digital inputs are internally disabled so that is not necessary to shut down CLK and SCLK. To exit Power-Down mode, return SYNC/PDWN high on the rising edge of CLK.

The ADS1271 uses a chopper-stabilized modulator to provide inherently very low offset drift. To further minimize offset, the ADS1271 automatically performs an offset self-calibration when exiting Power-Down mode. When power down completes, the offset self-calibration begins with the inputs AINP and AINN automatically disconnected from the signal source and internally shorted together. There is no need to modify the signal source applied to the analog inputs during this calibration. It is critical for the reference voltage to be stable when exiting Power-Down mode; otherwise, the calibration will be corrupted.

SBAS306F − NOVEMBER 2004 − REVISED OCTOBER 2007

The offset self-calibration only removes offset errors internal to the device, not offset errors due to external sources.

NOTE: When an offset self-calibration is performed, the resulting offset value will vary each time within the peak-to-peak noise range of the converter. In High-Speed mode, this is typically 178 LSBs.

The offset calibration value is cleared whenever the device mode is changed (for example, from High-Speed mode to High-Resolution mode).

When using the SPI format, **DRDY** will stay high after exiting Power-Down mode while the digital filter settles, as shown in Figure 52.

When using the Frame-Sync format, DOUT will stay low after exiting Power-Down mode while the digital filter settles, as shown in Figure 53.

NOTE: In Power-Down mode, the inputs of the ADS1271 must be driven (do not float) and the device drives the outputs driven to a DC level.

Figure 52. Power-Down Timing for SPI format

Figure 53. Power-Down Timing for Frame-Sync Format

POWER-UP SEQUENCE

The analog and digital supplies should be applied before any analog or digital input is driven. The power supplies may be sequenced in any order. Once the supplies and the voltage reference inputs have stabilized, data can be read from the device.

FREQUENCY RESPONSE

The digital filter sets the overall frequency response. The filter uses a multi-stage FIR topology to provide linear phase with minimal passband ripple and high stopband attenuation. The oversampling ratio of the digital filter (that is, the ratio of the modulator sampling to the output data rate: f_{MOD}/f_{DATA}) is a function of the selected mode, as shown in Table 7. f_{MOD} is CLK/2, CLK/4, or CLK/8, depending on the mode.

Table 7. Oversampling Ratio versus Mode

High-Speed and Low-Power Modes

The digital filter configuration is the same in both High-Speed and Low-Power modes with the oversampling ratio set to 64. Figure 54 shows the frequency response in High-Speed and Low-Power modes normalized to f_{DATA}. Figure 55 shows the passband ripple. The transition from passband to stop band is illustrated in Figure 56. The overall frequency response repeats at 64x multiples of the modulator frequency f_{MOD} , as shown in Figure 57. These image frequencies, if present in the signal and not externally filtered, will fold back (or alias) into the passband, causing errors. The stop-band of the ADS1271 provides 100dB attenuation of frequencies that begin just beyond the passband and continue out to f_{MOD} . Placing an antialiasing, low-pass filter in front of the ADS1271 inputs is recommended to limit possible high-amplitude out-of-band signals and noise.

Figure 54. Frequency Response for High-Speed and Low-Power Modes

Figure 55. Passband Response for High-Speed and Low-Power Modes

Figure 57. Frequency Response Out to f_{MOD} for **High-Speed and Low-Power Modes**

High-Resolution Mode

The oversampling ratio is 128 in High-Resolution mode. Figure 58 shows the frequency response in High-Resolution mode normalized to f_{DATA}. Figure 59 shows the passband ripple, and the transition from passband to stop band is illustrated in Figure 60. The overall frequency response repeats at multiples of the modulator frequency f_{MOD}, (128 \times f_{DATA}), as shown in Figure 61. The stop band of the ADS1271 provides 100dB attenuation of frequencies that begin just beyond the passband and continue out to f_{MOD}. Placing an antialiasing, low-pass filter in front of the ADS1271 inputs is recommended to limit possible high-amplitude out-of-band signals and noise.

Figure 58. Frequency Response for High-Resolution Mode

Table 8. Antialiasing Filter Order Image Rejection

ANTIALIASING	IMAGE REJECTION (dB) $(f_{-3dB}$ at f_{DATA})	
FILTER ORDER	HS, LP	HR
	39	45
	75	
	111	129

PHASE RESPONSE

The ADS1271 incorporates a multiple stage, linear phase digital filter. Linear phase filters exhibit constant delay time versus input frequency (constant group delay). This means the time delay from any instant of the input signal to the same instant of the output data is constant and is independent of input signal frequency. This behavior results in essentially zero phase errors when analyzing multi-tone signals.

SETTLING TIME

As with frequency and phase response, the digital filter also determines settling time. Figure 62 shows the output settling behavior after a step change on the analog inputs normalized to conversion periods. The X axis is given in units of conversion. Note that after the step change on the input occurs, the output data changes very little prior to 30 conversion periods. The output data is fully settled after 76 conversion periods for High-Speed and Low-Power modes, and 78 conversions for High-Resolution mode.

Figure 62. Settling Time for All Power Modes

DATA FORMAT

The ADS1271 outputs 24 bits of data in two's complement format.

A positive full-scale input produces an output code of 7FFFFFh, and the negative full-scale input produces an output code of 800000h. The output clips at these codes for signals exceeding full-scale. Table 9 summarizes the ideal output codes for different input signals.

(1) Excludes effects of noise, INL, offset and gain errors.

SERIAL INTERFACE

Data is retrieved from the ADS1271 using the serial interface. To provide easy connection to either microcontrollers or DSPs, two formats are available for the interface: SPI and Frame-Sync. The FORMAT pin selects the interface. The same pins are used for both interfaces (SCLK, DRDY/FSYNC, DOUT and DIN), though their respective functionality depends on the particular interface selected.

SPI SERIAL INTERFACE

The SPI-compatible format is a simple read-only interface. Data ready for retrieval is indicated by the DRDY output and is shifted out on the falling edge of SCLK, MSB first. The interface can be daisy-chained using the DIN input when using multiple ADS1271s. See the Daisy-Chaining section for more information.

SCLK (SPI Format)

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. The device shifts data out on the falling edge and the user shifts this data in on the

rising edge. Even though the SCLK input has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data. SCLK should be held low after data retrieval. SCLK may be run as fast as the CLK frequency. SCLK may be either in free-running or stop-clock operation between conversions. For best performance, limit f_{SCLK}/f_{CLK} to ratios of 1, 1/2, 1/4, 1/8, etc. When the device is configured for modulator output, SCLK becomes the modulator clock output (see the Modulator Output section).

For the f_{SCLK}/f_{CLK} ratio of 1, care must be observed that these signals are not tied together. After Power On, SCLK remains an output until a few clocks have been received on the CLK input.

DRDY/FSYNC

In the SPI format, this pin functions as the DRDY output. It goes low when data is ready for retrieval and then returns high on the falling edge of the first subsequent SCLK. If data is not retrieved (that is, SCLK is held low), DRDY will pulse high just before the next conversion data is ready, as shown in Figure 63. The new data is loaded within the ADS1271 one CLK cycle before DRDY goes low. All data must be shifted out before this time to avoid being overwritten.

Figure 63. DRDY Timing with No Readback

DOUT

The conversion data is shifted out on DOUT. The MSB data is valid on DOUT when DRDY goes low. The subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining, the data shifted in using DIN will appear on DOUT after all 24 bits have been shifted out. When the device is configured for modulator output, DOUT becomes the modulator data output (see the Modulator Output section).

DIN

This input is used when multiple ADS1271s are to be daisy-chained together. The DOUT pin of the first device connects to the DIN pin of the next, etc. It can be used with either the SPI or Frame-Sync formats. Data is shifted in on the falling edge of SCLK. When using only one ADS1271, tie DIN low. See the Daisy-Chaining section for more information.

FRAME-SYNC SERIAL INTERFACE

Frame-Sync format is similar to the interface often used on audio ADCs. It operates in slave fashion—the user must supply framing signal FSYNC (similar to the left/right clock on stereo audio ADCs) and the serial clock SCLK (similar to the bit clock on audio ADCs). The data is output MSB first or left-justified. When using Frame-Sync format, the CLK, FSYNC and SCLK inputs must be synchronized together, as described in the following sub-sections.

SCLK (Frame-Sync Format)

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. Even though SCLK has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data. When using Frame-Sync format, SCLK must run continuously. If it is shut down, the data readback will be corrupted. Frame-Sync format requires a specific relationship between SCLK and FSYNC, determined by the mode shown in Table 10. When the device is configured for modulator output, SCLK becomes the modulator clock output (see the Modulator Output section).

Table 10. SCLK Period When Using Frame-Sync Format

DRDY/FSYNC

In Frame-Sync format, this pin is used as the FSYNC input. The frame-sync input (FSYNC) sets the frame period. The required FSYNC periods are shown in Table 11. For High-Speed mode, the FSYNC period must be 256 CLK periods. For both High-Resolution and Low-Power modes, the FSYNC period can be either 512 or 256 CLK periods; the ADS1271 will automatically detect which is being used. If the FSYNC period is not the proper value, data readback will be corrupted. It is recommended that FSYNC be aligned with the falling edge of SCLK.

Table 11. FSYNC Period

MODE	REQUIRED FSYNC PERIOD	
High-Speed	256 CLK Periods	
High-Resolution	256 or 512 CLK periods	
Low-Power	256 or 512 CLK periods	

DOUT

The conversion data is shifted out on DOUT. The MSB data becomes valid on DOUT on the CLK rising edge prior to FSYNC going high. The subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining, the data shifted in using DIN will appear on DOUT after all 24 bits have been shifted out. When the device is configured for modulator output, DOUT becomes the modulator data output (see the Modulator Output section).

DIN

This input is used when multiple ADS1271s are to be daisy-chained together. It can be used with either SPI or Frame-Sync formats. Data is shifted in on the falling edge of SCLK. When using only one ADS1271, tie DIN low.See the Daisy-Chaining section for more information.

DAISY-CHAINING

Multiple ADS1271s can be daisy-chained together to simplify the serial interface connections. The DOUT of one ADS1271 is connected to the DIN of the next ADS1271. The first DOUT provides the output data and the last DIN in the chain is connected to ground. A common SCLK is used for all the devices in the daisy chain. Figure 64 shows an example of a daisy chain with four ADS1271s. Figure 65 shows the timing diagram when reading back in the SPI format. It takes 96 SCLKs to shift out all the data.

In SPI format, it is recommended to tie all the SYNC/PDWN inputs together, which forces synchronization of all the devices. It is only necessary to monitor the DRDY output of one device when multiple devices are configured this way.

In Frame-Sync format, all of the devices are driven to synchronization by the FSYNC and SCLK inputs. However, to ensure synchronization to the same f_{CLK} cycle, it is recommended to tie all SYNC/PDWN inputs together.

The device clocks the SYNC/PDWN pin on the falling edge of f_{CLK}. To ensure exact synchronization, the SYNC/PDWN pin should transition on the rising edge of f_{CLK}

Since DOUT and DIN are both shifted on the falling edge of SCLK, the propagation delay on DOUT creates the setup time on DIN. Minimize the skew in SCLK to avoid timing violations. See Mode Selection section for MODE pin use when daisy-chaining.

The SPI format offers the most flexibility when daisy-chaining because there is more freedom in setting the SCLK frequency. The maximum number of ADS1271s that can be daisy-chained is determined by dividing the conversion time ($1/f_{DATA}$) by the time needed to read back all 24 bits $(24 \times 1/\sqrt{5})$.

Consider the case where:

 $f_{\text{CIX}} = 27$ MHz

mode = High-Resolution (52,734SPS)

 $format = SPI$

 $f_{\text{SCI K}} = 27 \text{MHz}$

The maximum length of the daisy-chain is:

 $27MHz/(24 \times 52,734SPS) = 21.3$

Rounding down gives 21 as the maximum number of ADS1271s that can be daisy-chained.

Daisy-chaining also works in Frame-Sync format, but the maximum number of devices that can be daisy-chained is less than when using the SPI format. The ratio between the frame period and SCLK period is fixed, as shown in Table 10. Using these values, the maximum number of devices is two for High-Speed and Low-Power modes, and five for High-Resolution mode.

MODULATOR OUTPUT

The ADS1271 incorporates a 6th-order, single-bit, chopper-stabilized modulator followed by a multi-stage digital filter, which yields the conversion results. The data stream output of the modulator is available directly, bypassing the internal digital filter. In this mode, an external digital filter implemented in an ASIC, FPGA, or similar device is required. To invoke the modulator output, float the FORMAT pin and tie DIN to DVDD. DOUT then becomes the modulator data stream output and SCLK becomes the modulator clock output. The DRDY/FSYNC pin becomes an unused output and can be ignored. The normal operation of the Frame-Sync and SPI interfaces is disabled, and the functionality of SCLK changes from an input to an output, as shown in Figure 66. Note that modulator output mode is specified for the B grade device only.

Figure 66. Modulator Output (B-Grade Device)

In modulator output mode, the frequency of the SCLK clock output depends on the mode selection of the ADS1271. Table 12 lists the modulator clock output frequency versus device mode.

Table 12. Modulator Output Clock Frequencies

Figure 67 shows the timing relationship of the modulator clock and data outputs.

Figure 67. Modulator Output Timing

APPLICATION INFORMATION

To obtain the specified performance from the ADS1271, the following layout and component guidelines should be considered.

- 1. Power Supplies: The device requires two power supplies for operation: DVDD and AVDD. The allowed range for DVDD is 1.65V to 3.6V, and AVDD is restricted to 4.75V to 5.25V. Best performance is achieved when $DVDD = 1.8V$. For both supplies, use a 10µF tantalum capacitor, bypassed with a 0.1µF ceramic capacitor, placed close to the device pins. Alternatively, a single 10µF ceramic capacitor can be used. The supplies should be relatively free of noise and should not be shared with devices that produce voltage spikes (such as relays, LED display drivers, etc.). If a switching power supply source is used, the voltage ripple should be low (< 2mV). The power supplies may be sequenced in any order.
- 2. Ground Plane: A single ground plane connecting both AGND and DGND pins can be used. If separate digital and analog grounds are used, connect the grounds together at the converter.
- 3. Digital Inputs: It is recommended to source terminate the digital inputs to the device with $50Ω$ series resistors. The resistors should be placed close to the driving end of digital source (oscillator, logic gates, DSP, etc.) This helps to reduce ringing on the digital lines, which may lead to degraded ADC performance.
- 4. Analog/Digital Circuits: Place analog circuitry (input buffer, reference) and associated tracks together, keeping them away from digital circuitry (DSP, microcontroller, logic). Avoid crossing digital tracks across analog tracks to reduce noise coupling and crosstalk.

SBAS306F − NOVEMBER 2004 − REVISED OCTOBER 2007

- 5. Reference Inputs: It is recommended to use a minimum 10µF tantalum with a 0.1µF ceramic capacitor directly across the reference inputs, VREFP and VREFN. The reference input should be driven by a low-impedance source. For best performance, the reference should have less than $3\mu V_{RMS}$ broadband noise. For references with noise higher than this, external reference filtering may be necessary.
- 6. Analog Inputs: The analog input pins must be driven differentially to achieve specified performance. A true differential driver or transformer (AC applications) can be used for this purpose. Route the analog inputs tracks (AINP, AINN) as a pair from the buffer to the converter using short, direct tracks and away from digital tracks.

A 1nF to 10nF capacitor should be used directly across the analog input pins, AINP and AINN. A low-k dielectric (such as COG or film type) should be used to maintain low THD. Capacitors from each analog input to ground should be used. They should be no larger than 1/10 the size of the difference capacitor (typically 100pF) to preserve the AC common-mode performance.

7. Component Placement: Place the power supply, analog input, and reference input bypass capacitors as close as possible to the device pins. This is particularly important for the small-value ceramic capacitors. Surface-mount components are recommended to avoid the higher inductance of leaded components.

Figure 68 to Figure 70 illustrate basic connections and interfaces that can be used with the ADS1271.

Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

IMENTS

PACKAGING INFORMATION

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details. **TBD:** The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute ^a license from TI to use such products or services or ^a warranty or endorsement thereof. Use of such information may require ^a license from ^a third party under the patents or other intellectual property of the third party, or ^a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where ^a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
