

### FEATURES

- Compresses/expands 64kbps PCM voice to/from either 32kbps, 24kbps, or 16kbps
- Dual fully independent channel architecture; device can be programmed to perform either:
  - two expansions
  - two compressions
  - one expansion and one compression
- Interconnects directly to combo-codec devices
- Input to output delay is less than 375µs
- Simple serial port used to configure the device
- On-board time-slot assigner-circuit (TSAC) function allows data to be input/output at various time slots
- Supports Channel Associated Signaling
- Each channel can be independently idled or placed into bypass
- Available hardware mode requires no host processor; ideal for voice storage applications
- Backward-compatible with the DS2165Q ADPCM processor chip
- Single +5V supply; low-power CMOS technology
- Available in 28-pin PLCC

### PIN ASSIGNMENT (Top View)

### DESCRIPTION

The DS2164Q ADPCM processor chip is a dedicated digital-signal-processing (DSP) chip that has been optimized to perform adaptive-differential pulse-code modulation (ADPCM) speech compression at three different rates. The chip can be programmed to compress (expand) 64kbps voice data down to (up from) either 32kbps, 24kbps, or 16kbps. The compression to 32kbps follows the algorithm specified by CCITT Recommendation G.726. The DS2164Q can switch compression algorithms on-the-fly. This allows the user to make maximum use of the available bandwidth on a dynamic basis.

**Note:** Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device may be simultaneously available through various sales channels. For information about device errata, click here: <http://www.maxim-ic.com/errata>.

## OVERVIEW

The DS2164Q contains three major functional blocks: a high performance (10 MIPS) DSP engine, two independent PCM interfaces (X and Y) that connect directly to serial time-division-multiplexed (TDM) backplanes, and a serial port that can configure the device on-the-fly by an external controller. A 10MHz master clock is required by the DSP engine. The DS2164Q can be configured to perform either two expansions, two compressions, or one expansion and one compression. The PCM/ADPCM data interfaces support data rates from 256kHz to 4.096MHz. Typically, the PCM data rates are 1.544MHz for  $\mu$ -law and 2.048MHz for A-law. Each channel on the device samples the serial input PCM or ADPCM bit stream during a user-programmed input time slot, processes the data and outputs the result during a user-programmed output time slot.

Each PCM interface has a control register that specifies functional characteristics (compress, expand, bypass, and idle), data format ( $\mu$ -law or A-law), and algorithm reset control. With the SPS pin strapped high, the software mode is enabled and the serial port can be used to configure the device. In this mode, a novel addressing scheme allows multiple devices to share a common 3-wire control bus, simplifying system-level interconnect.

With SPS low, the hardware mode is enabled. This mode disables the serial port and maps certain control register bits to some of the address and serial port pins. Under the hardware mode, no external host controller is required and all PCM/ADPCM input and output time slots default to time slot 0.

## HARDWARE RESET

$\overline{\text{RST}}$  allows the user to reset both channel algorithms and the contents of the internal registers. This pin must be held low for at least 1ms on system power-up after the master clock is stable to ensure that the device has initialized properly.  $\overline{\text{RST}}$  should also be asserted when changing to or from the hardware mode.  $\overline{\text{RST}}$  clears all bits of the control register for both channels except the IPD bits; the IPD bits for both channels are set to 1.

## SOFTWARE MODE

Connecting SPS high enables the software mode. In this mode, an external host controller writes configuration data to the DS2164Q by the serial port through inputs SCLK, SDI, and  $\overline{\text{CS}}$  (Figure 2). Each write to the DS2164Q is either a 2-byte write or a 4-byte write. A 2-byte write consists of the address/command byte (ACB), followed by a byte to configure the control register (CR) for either the X or Y channel. The 4-byte write consists of the ACB, followed by a byte to configure the CR, and then 1 byte to set the input time slot and another byte to set the output time slot.

## ADDRESS/COMMAND BYTE

In the software mode, the address/command byte is the first byte written to the serial port; it identifies which of the 64 possible ADPCM processors sharing the port wiring is to be updated. Address data must match that at inputs A0 to A5. If no match occurs, the device ignores the following configuration data. If an address match occurs, the next 3 bytes written are accepted as control, input and output time slot data. Bit ACB.6 determines which side (X or Y) of the device is to be updated. The PCM and ADPCM outputs are tri-stated during register updates.

## CONTROL REGISTER

The control register establishes idle, algorithm reset, bypass, data format, and channel coding for the selected channel.

The X-side and Y-side PCM interfaces can be independently disabled (output tri-stated) by IPD. When IPD is set for both channels, the device enters a low-power standby mode. In this mode, the serial port must not be operated faster than 39kHz.

ALRST resets the algorithm coefficients for the selected channel to their initial values. ALRST is cleared by the device when the algorithm reset is complete.

**Table 1. PIN DESCRIPTION**

PIN	SYMBOL	TYPE	FUNCTION

25	FSY	I	<b>Y Frame Sync.</b> 8kHz frame sync for the Y-side PCM interface.
26	CLKY	I	<b>Y Data Clock.</b> Data clock for the Y-side PCM interface; must be synchronous with FSY.
27	YIN	I	<b>Y Data In.</b> Sampled on falling edge of CLKY during selected time slots.
28	VDD	—	<b>Positive Supply.</b> 5.0V

**Figure 1. BLOCK DIAGRAM****Figure 2. SERIAL PORT WRITE**

**Note:** A 2-byte write is shown.

The bypass feature is enabled when  $\overline{\text{BYP}}$  is set and  $\overline{\text{IPD}}$  is cleared. During bypass, no expansion or compression occurs. Bypass operates on byte-wide (8 bits) slots when  $\overline{\text{CP/EX}}$  is set and on nibble-wide (4 bits) slots when  $\overline{\text{CP/EX}}$  is cleared.

A-law ( $\overline{\text{U/A}} = 0$ ) and  $\mu$ -law ( $\overline{\text{U/A}} = 1$ ) PCM coding is independently selected for the X and Y channels by CR.2. If  $\overline{\text{BYP}}$  and  $\overline{\text{IPD}}$  are cleared, then  $\overline{\text{CP/EX}}$  determines if the input data is to be compressed or expanded.

## TIME SLOT ASSIGNMENT/ORGANIZATION

On-board counters establish when PCM and ADPCM I/O occur. The counters are programmed by the time slot registers. Time slot size (number of bits wide) is determined by the state of  $CP/\overline{EX}$ . The number of time slots available is determined by the state of both  $CP/\overline{EX}$  and  $U/\overline{A}$  (Figures 7 through 10). For example, if the X channel is set to compress ( $CP/\overline{EX} = 1$ ) and it is set to expect  $\mu$ -law data ( $U/\overline{A} = 1$ ), then the input port (XIN) is set up for 32 8-bit time slots and the output port (XOUT) is set up for 64 4-bit time slots. The time slot organization is not dependent on which algorithm has been selected.

**Note:** Time slots are counted from the frame sync signal starting at the first rising edge of either CLKX or CLKY after the frame sync.

**Figure 8.  $\mu$ -LAW ADPCM INTERFACE**

## Figure 9. A-LAW PCM INTERFACE

## Figure 10. A-LAW ADPCM INTERFACE

## HARDWARE MODE

The hardware mode is intended for applications that do not have an external controller available or do not require the extended features offered by the serial port. Connecting the SPS pin to  $V_{SS}$  disables the serial port, clears all internal register bits, and maps the IPD,  $U/\bar{A}$ , and  $CP/\bar{EX}$  bits for both channels to external bits (Table 3). In the hardware mode, both the input and output time slots default to time slot 0.

**Table 3. HARDWARE MODE**

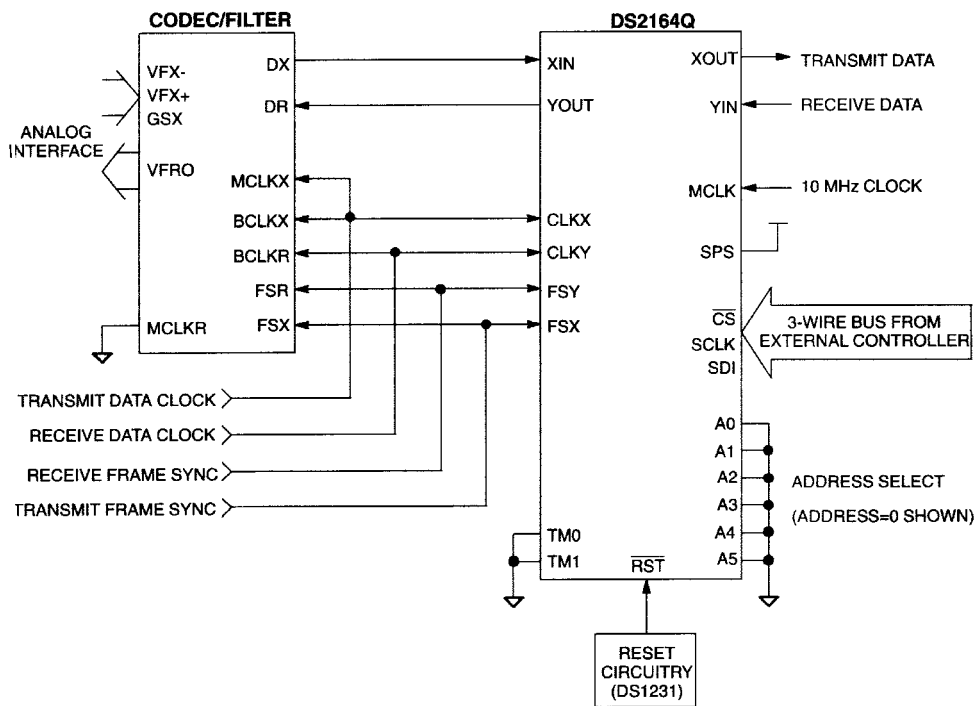

PIN		REGISTER LOCATION	FUNCTION
#	NAME		
4	A0	$CP/\bar{EX}$ (Channel X)	Channel X Coding Configuration 0 = Expand 1 = Compress
5	A1	AS0/AS1/AS2 (Channel X and Y)	Algorithm Select (Table 4)
6	A2	$U/\bar{A}$ (Channel X)	Channel X Data Format 0 = A-law 1 = $\mu$ -law
7	A3	$CP/\bar{EX}$ (Channel Y)	Channel Y Coding Configuration 0 = Expand 1 = Compress
8	A4	AS0/AS1/AS2 (Channel X and Y)	Algorithm Select (Table 4)
9	A5	$U/\bar{A}$ (Channel Y)	Channel Y Data Format 0 = A-law 1 = $\mu$ -law
18	SDI	IPD (Channel Y)	Channel Y Idle Select 0 = Channel Active 1 = Channel Idle
19	$\bar{CS}$	IPD (Channel X)	Channel X Idle Select 0 = Channel Active 1 = Channel Idle

### NOTES:

- 1) SCLK must be connected to  $V_{SS}$  when the hardware mode is selected.
- 2) When both channels are idled, power consumption is significantly reduced.
- 3) The DS2164Q powers up within 800ms after either channel is returned to active from an idle state.

**Table 4. ALGORITHM SELECT FOR HARDWARE MODE**

ALGORITHM	CONFIGURATION OF A1 AND A4
64kbps to/from 32kbps	Connect both A1 and A4 to V <sub>SS</sub> .
64kbps to/from 24kbps	Hold A1 and A4 low during a hardware reset; take both A1 and A4 high after the $\overline{\text{RST}}$ pin has returned high (allow 3 $\mu$ s after $\overline{\text{RST}}$ returns high before taking A1 and A4 high).
64kbps to/from 16kbps	Connect both A1 and A4 to V <sub>DD</sub> .

## PCM AND ADPCM INPUT/OUTPUT

Since the organization of the input and output time slots on the DS2164Q does not depend on the algorithm selected, it always assumes that PCM input and output are in 8-bit bytes and that ADPCM input and output are in 4-bit bytes. Figure 12 demonstrates how the DS2164Q handles the I/O for the three different algorithms. In the figure, it is assumed that channel X is in the compression mode ( $CP/\overline{EX} = 1$ ) and channel Y is in the expansion mode ( $CP/\overline{EX} = 0$ ). Also, it is assumed that both the input and output time slots for both channels are set to 0.

**Figure 12. PCM AND ADPCM I/O EXAMPLE**

**Note 1:** The bit after the LSB in the 24kbps ADPCM output is only a 1 when the DS2164Q is operated in the software mode and is programmed to perform 24kbps compression; in all other configurations, it is a 0.

## **TIME SLOT RESTRICTIONS**

Under certain conditions, the DS2164Q does contain some restrictions on the output time slots that are available. These restrictions are covered in detail in a separate application note. No restrictions occur if the DS2164Q is operated in the hardware mode.

## **INPUT TO OUTPUT DELAY**

With all three compressions algorithms, the total delay, from the time the PCM data sample is captured by the DS2164Q to the time it is output, is always less than 375 $\mu$ s. The exact delay is determined by the input and output time slots selected for each channel.

## **CHANNEL ASSOCIATED SIGNALING**

The DS2164Q supports Channel Associated Signaling (CAS) through its ability to automatically change from the 32kbps compression algorithm to the 24kbps algorithm. If the DS2164Q is configured to perform the 32kbps algorithm, then in both the hardware and software mode it senses the frame sync inputs (FSX and FSY) for a double-wide frame-sync pulse. Whenever the DS2164Q receives a double-wide pulse, it automatically switches from the 32kbps algorithm to the 24kbps algorithm. Switching to the 24kbps algorithm allows the user to insert signaling data into the LSB bit position of the ADPCM output because this bit does not contain any useful speech information.

## **ON-THE-FLY ALGORITHM SELECTION**

In the software mode, the user can switch between the three available algorithms on-the-fly. That is, the DS2164Q does not need to be reset or stopped to make the change from one algorithm to another. The DS2164Q reads the control register before it starts to process each PCM or ADPCM sample. If the user wishes to switch algorithms, then the control register must be updated by the serial port before the first input sample to be processed with the new algorithm arrives at either XIN or YIN. The PCM and ADPCM outputs tri-state during register updates.

**ABSOLUTE MAXIMUM RATINGS\***

Voltage Range on Any Pin Relative to Ground	-1.0V to +7.0V
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-55°C to +125°C
Soldering Temperature Range	See IPC/JEDEC J-STD-020A

\*This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operation sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time can affect reliability.

**RECOMMENDED DC OPERATING CONDITIONS**(T<sub>A</sub> = 0°C to +70°C)
