## description

The TWL2213 is a single-chip battery and power management solution for wireless handsets, pagers, personal data assistants (PDAs), and other battery-powered devices. For battery charging, the device incorporates a linear charger for single-cell Li-Ion and lithium polymer battery packs. Prior to charging, the TWL2213 initiates battery pack wake up and damaged cell detect functions. For deeply discharged batteries, the device performs precharge conditioning by trickle-charge to user-defined current settings. Once acceptable pack voltage is detected, TWL2213 applies a constant-current fast charge at a current level that is determined by a combination of an external sense resistor and user-programmable sense voltage. When the battery reaches the selected charge regulation voltage, TWL2213 maintains regulation until charging is terminated by a minimum current or a timer. During the entire charge cycle, TWL2213 monitors temperature by external thermistor and suspends charging if temperature exceeds a programmed range. Three programmable safety timers limit the precharge, constant-current, and total charge times.

For power management, the TWL2213 includes six low-dropout linear voltage regulators. One regulator is driven from the device's power on/off logic and incorporates a microcontroller reset function. Five low noise regulators include individually programmable output voltage and enable-disable. The TWL2213 can be powered from a battery or AC adapter. When an adapter is present, it supplies power to the device, allowing the system to function without battery.

TWL2213 also includes individually selectable drivers for three separate backlight LEDs, a ringer, and a vibrator motor. An internal 8-bit analog-to-digital converter (ADC) is accessible from external pins. The system microcontroller accesses all TWL2213 programming and status via the I<sup>2</sup>C serial interface.

The TWL2213 device is packaged in the Texas Instruments 48-terminal plastic thin quad flatpack (TQFP) package (PFB).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

#### detailed description

##### power on/off control

The power on/off control circuit controls the timing of the delayed power on reset. There are two different reset conditions: the manual power condition and the adapter power-on condition.

Under the manual-powered condition, if the power key is pressed, the PWRKIN signal goes high and V<sub>REG1</sub> (regulator 1 output) is enabled. After V<sub>REG1</sub> reaches 90% of its nominal output voltage, the TWL2213 starts the delayed reset process by charging the reset timing capacitor (CD1). When the voltage of CD1 reaches 1.2 V, the XRST signal is released by TWL2213 and is pulled high by an external pull-up resistor. This completes the reset process, and the external controller operates in normal condition. While the PWRKIN signal remains high, the power-on condition remains active. Before the PWRKIN signal goes low, the external controller must drive PSH high to retain power; otherwise, the TWL2213 starts the delay power-off process by charging the CD2 timing capacitor. After the voltage of CD2 reaches 1.2 V and no valid PSH signal is received, the device is powered off.

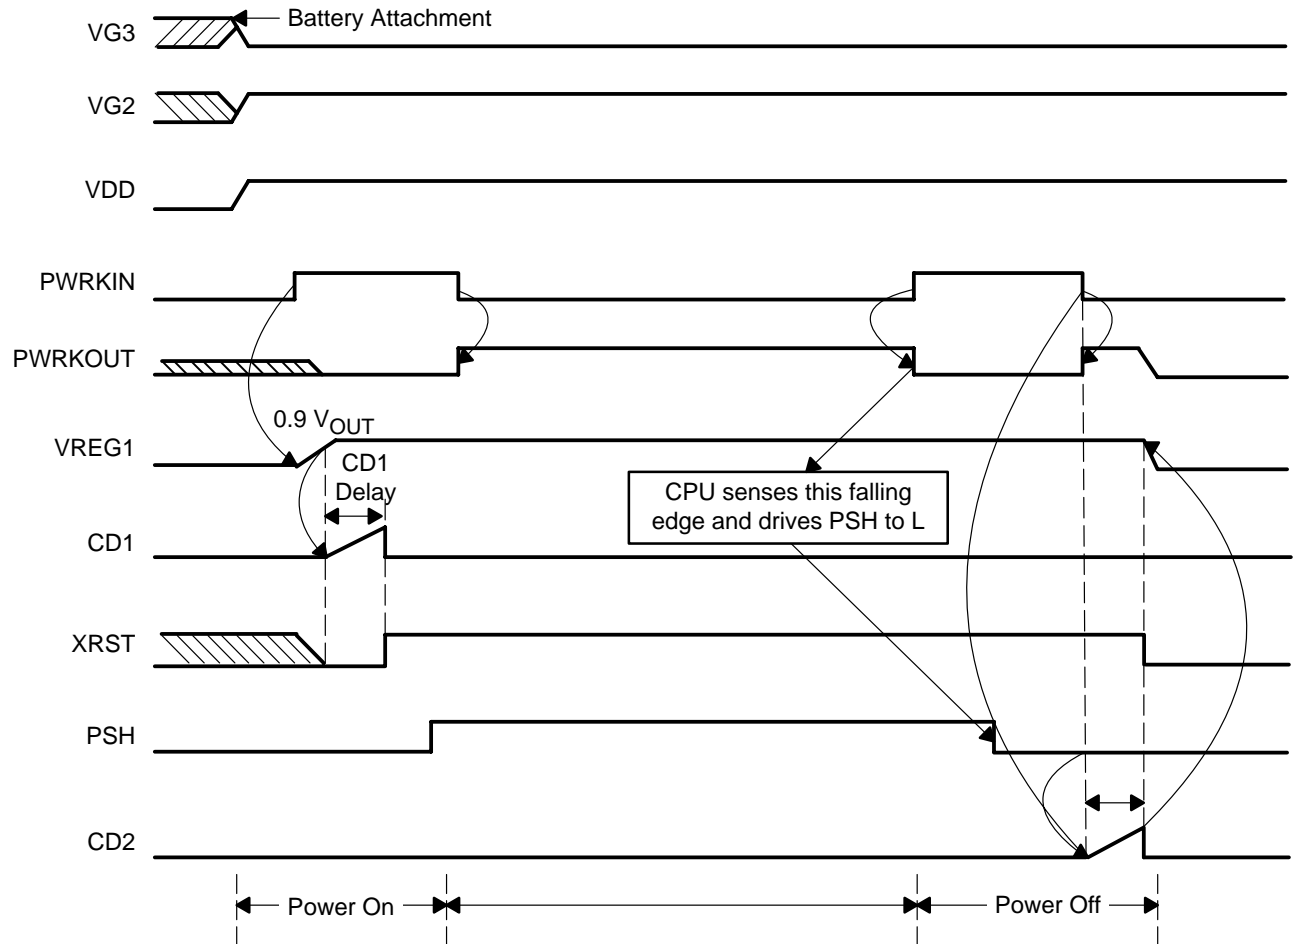

Under the adapter power-on condition, no battery is attached to the device. During the power-off state, after the adapter is attached, the output of V<sub>REG1</sub> (regulator 1 output) is automatically enabled. After V<sub>REG1</sub> reaches 90% of its nominal output voltage, the TWL2213 starts the delayed reset process by charging the reset timing capacitor (CD1). When the voltage of CD1 reaches 1.2 V, the XRST signal is released by TWL2213 and is pulled high by an external pull-up resistor. This completes the reset process, and the external controller operates in normal condition. The external controller must drive PSH high to retain power; otherwise, the TWL2213 starts the delay power-off process by charging the CD2 timing capacitor. After the voltage of CD2 reaches 1.2 V and no valid PSH signal is received, the device is powered off.

During the power-on state, the device generates an output signal (PWRKOUT) with the inverted polarity to PWRKIN. The external controller can use the PWRKOUT signal to detect power key action.

**POWER SUPPLY MANAGEMENT IC AND**  
**Li-Ion BATTERY CHARGE CONTROL**

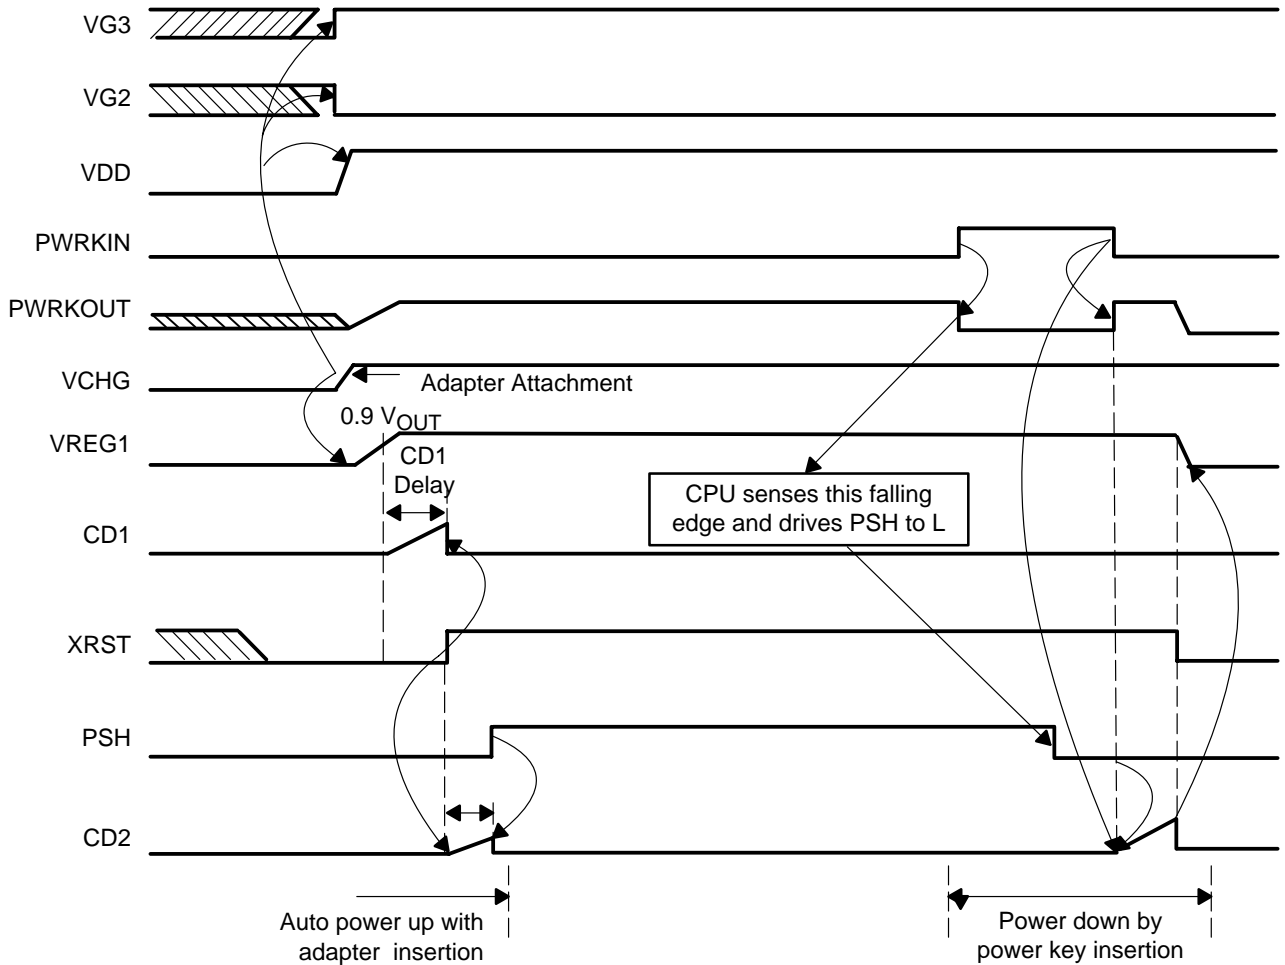

SLVS280 – MARCH 2001

**detailed description (continued)**

**Figure 1. Power-On/-Off Sequence**

**detailed description (continued)**

**Figure 2. Power-On/Off Sequence**

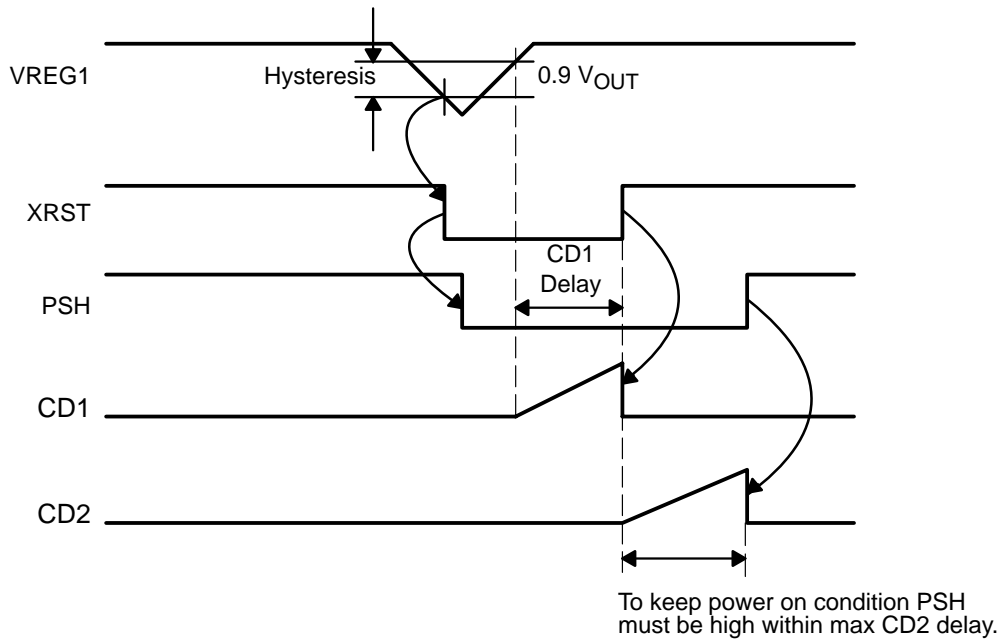

**reset controller**

The reset controller performs two major functions; one is to control the timing of delayed power-on reset, and the other is to monitor the  $V_{REG1}$  level.

The delay reset process is started when  $V_{REG1}$  (regulator 1 output) reaches 90% of its nominal output voltage level. The delay time of the reset output (XRST) can be adjusted by external timing capacitance (CD1) (see Figure 1, and Figure 2).

During system active state when  $V_{REG1}$  drops below  $0.9V_{nominal} - \text{hysteresis}$ , XRST is driven low. If  $V_{REG1}$  reaches 90% of its nominal output voltage level again, the delayed reset process starts over.

**detailed description (continued)**

**Figure 3.  $V_{REG1}$  Monitoring of Reset Control**

**regulator 1**

This regulator is automatically enabled after the power-on process is complete. It stays enabled until the power-off condition occurs. Regulator 1 supplies power to the microprocessor. The nominal output voltage is 2.8 V, and the maximum output current is 150 mA. It requires an output capacitor in the range of 4.7  $\mu\text{F}$ –10  $\mu\text{F}$  with an equivalent serial resistance (ESR) less than 6  $\Omega$ .

**regulator 6**

This regulator output voltage can be enabled by I<sup>2</sup>C/SPI by attaching the CONT terminal to  $V_{DD}$ . Attaching CONT to GND makes this regulator automatically enabled with power on. The output voltage is programmed by I<sup>2</sup>C/SPI. The maximum out current of 100 mA requires an output capacitor in range of 4.7  $\mu\text{F}$ –10  $\mu\text{F}$ , with ESR in the range of 1  $\Omega$ –6  $\Omega$ . The output voltage ranges from 2.5 V to 3 V.

**regulators 2, 3, 4, and 5**

Regulators 2, 3, 4, and 5 are output voltages programmed and enabled by I<sup>2</sup>C. The output voltage ranges from 2.3 V to 3 V in 100-mV steps. The maximum output current for regulators 2 and 3 is 80 mA, for regulator 4 it is 120 mA, and for regulator 5 it is 150 mA. The default output voltage for all regulators is 3 V. These regulators have very low output noise; this noise level is suitable for powering up the RF block, which requires an output capacitor in the range of 4.7  $\mu\text{F}$ –10  $\mu\text{F}$  with an ESR less than 6  $\Omega$ .

**vibrator driver**

The TWL2213 device has incorporated a vibrator driver with selectable output voltage and current. This integrated vibrator driver has the same feature as the other load dropout (LDO) regulators. The vibrator is enabled by I<sup>2</sup>C. The output voltage can be selected by tying the SEL terminal to  $V_{DD}$  or GND. If the SEL terminal is tied to  $V_{DD}$ , the output voltage is set to 3 V. If the SEL terminal is tied to GND, the output voltage is set to 1.3 V.

**detailed description (continued)**

**LED driver**

The TWL2213 device provides the capability of driving three LEDs. These drivers, enabled by I<sup>2</sup>C, can drive currents of 160 mA, 20 mA, and 10 mA individually with a maximum voltage drop of 0.8 V.

**ringer driver**

The TWL2213 device provides the capability of driving a ringer. It is enabled by I<sup>2</sup>C and uses an N-channel FET with a maximum resistance of 3 Ω.

**I<sup>2</sup>C**

This block provides I<sup>2</sup>C interface to the external devices.

**battery charger control**

This block provides the necessary signals to control the external circuits that perform the charger function. The charging activities include battery pack wake up, precharge, fast charge, and battery temperature monitoring. This block also provides two ADC inputs for general measurement purpose. The input voltage level is from 0 to 2 volts. This block also includes an oscillator generator circuit, which generates the clocks for the device. The nominal frequency of the main clock is 500 kHz. It requires an external capacitor of 470 pF.

**reference system**

This block provides voltage reference and bias current for the internal circuitry.

**absolute maximum ratings over operating free-air temperature (unless otherwise noted)†**

VCHG to GND (terminal 34)	–0.3 V to 12 V
All other terminals relative to GND	–0.3 V to 6.5 V
Operating ambient temperature	–25°C to 85°C
Operating junction temperature range, T <sub>J</sub>	–25°C to 150°C
Storage temperature range, T <sub>stg</sub>	–55°C to 150°C
Soldering temperature (for 10 seconds)	260°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

# TWL2213CA POWER SUPPLY MANAGEMENT IC AND Li-Ion BATTERY CHARGE CONTROL

SLVS280 – MARCH 2001

## I<sup>2</sup>C bus protocols

The TWL2213 serial interface is designed to be I<sup>2</sup>C bus compatible, operating in the slave mode. This interface consists of the following terminals:

**CLK:** I<sup>2</sup>C bus serial clock. This input synchronizes the control data transfer from and to the microprocessor.

**DATA:** I<sup>2</sup>C bus serial address/data input/output. This is a bidirectional terminal that transfers registers, control addresses, and data into and out of the microprocessor. This terminal is an open drain and requires a pullup resistor of 10 k $\Omega$  to V<sub>REG1</sub>.

The TWL2213 device has a fixed device select addresses of E4h for write mode and E5h for read mode. For normal data transfer, DATA is allowed to change only when CLK is low. Changes when CLK is high are reserved for indicating the start and stop conditions. Data transfer may be initiated only when the bus is not busy (both DATA and CLK lines remain high). During data transfer, the data line must remain stable whenever the clock line is at high. There is one clock pulse per bit of data. Each data transfer is initiated with a start condition and terminated with a stop condition. When addressed, the TWL2213 device generates an acknowledge after the reception of each byte. The master device (microprocessor) must generate an extra clock pulse that is associated with the acknowledge bit. The TWL2213 device must pull down the DATA line during the acknowledge clock pulse so that the DATA line is at stable low state during the high period of the acknowledge clock pulse. The DATA line is at a stable low state during the high period of the acknowledge related clock pulse. Setup and hold times must be taken into account. During read operations, a master must signal the end of data to the slave by not generating an acknowledge bit on the last byte that was clocked out of the slave. In this case, the slave TWL2213 device must leave the data line high to enable the master to generate the stop condition.

**APPLICATION INFORMATION**

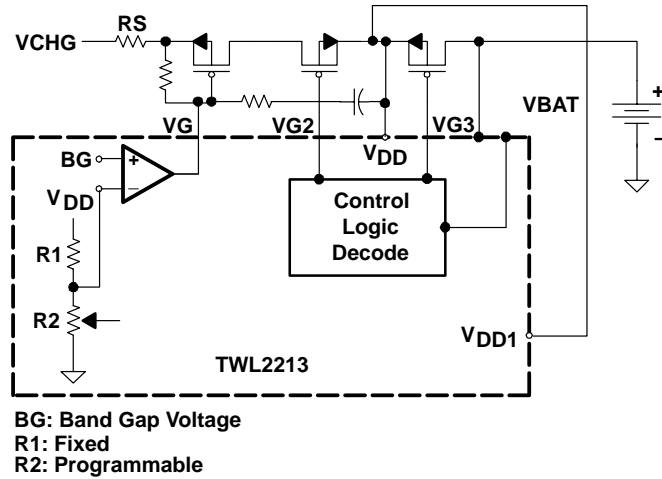

**Figure 10. Typical Application Circuit**

**APPLICATION INFORMATION**

**device power supply control ( $V_{DD1}$ )**

The TWL2213 device receives device power by regulating the VCHG input to 4.1 V or 4.2 V, whenever VCHG is available; otherwise, the device uses the VBAT input directly as device dc supply. The regulated voltage from VCHG is programmable through the I<sup>2</sup>C interface.

**Figure 11. Device Power Supply**

Condition 1: VCHG is on (VG = Active, VG2 = On, VG3 = Off)

$$V_{DD1} = BG \times \frac{R1 + R2}{R2} = 4.1 \text{ V or } 4.2 \text{ V}$$

TWL2213 device sets R2 value according to the programmed voltage level (4.1 V or 4.2 V).

Condition 2: VCHG is Off and VBAT applied (VG = High, VG2 = Off, VG3 = On)

$$V_{DD1} = VBAT$$

**battery charger**

The TWL2213 device provides a charger function for single cell Li-Ion battery packs. The charging activity starts with the battery pack wake-up cycle. If the wake-up cycle completes successfully, the charger starts the precharge function and slowly charges the battery to 3.2 V. If the battery is charged to 3.2 V within the time limit, the charger goes into the fast charge mode. The fast charge mode has two phases: 1) constant current mode (CC) and 2) constant voltage mode (CV). The charger starts CC mode with the maximal charging current until the battery voltage reaches the regulated voltage level. The charger is then switched to CV mode. During the CV mode, the TWL2213 device monitors the charging current; once it is below the programmed termination current level, the charger activity is terminated. The termination current level can be programmed at 10%, 20%, 30%, 40%, or 50% of the maximum charging current at the CC mode.

APPLICATION INFORMATION

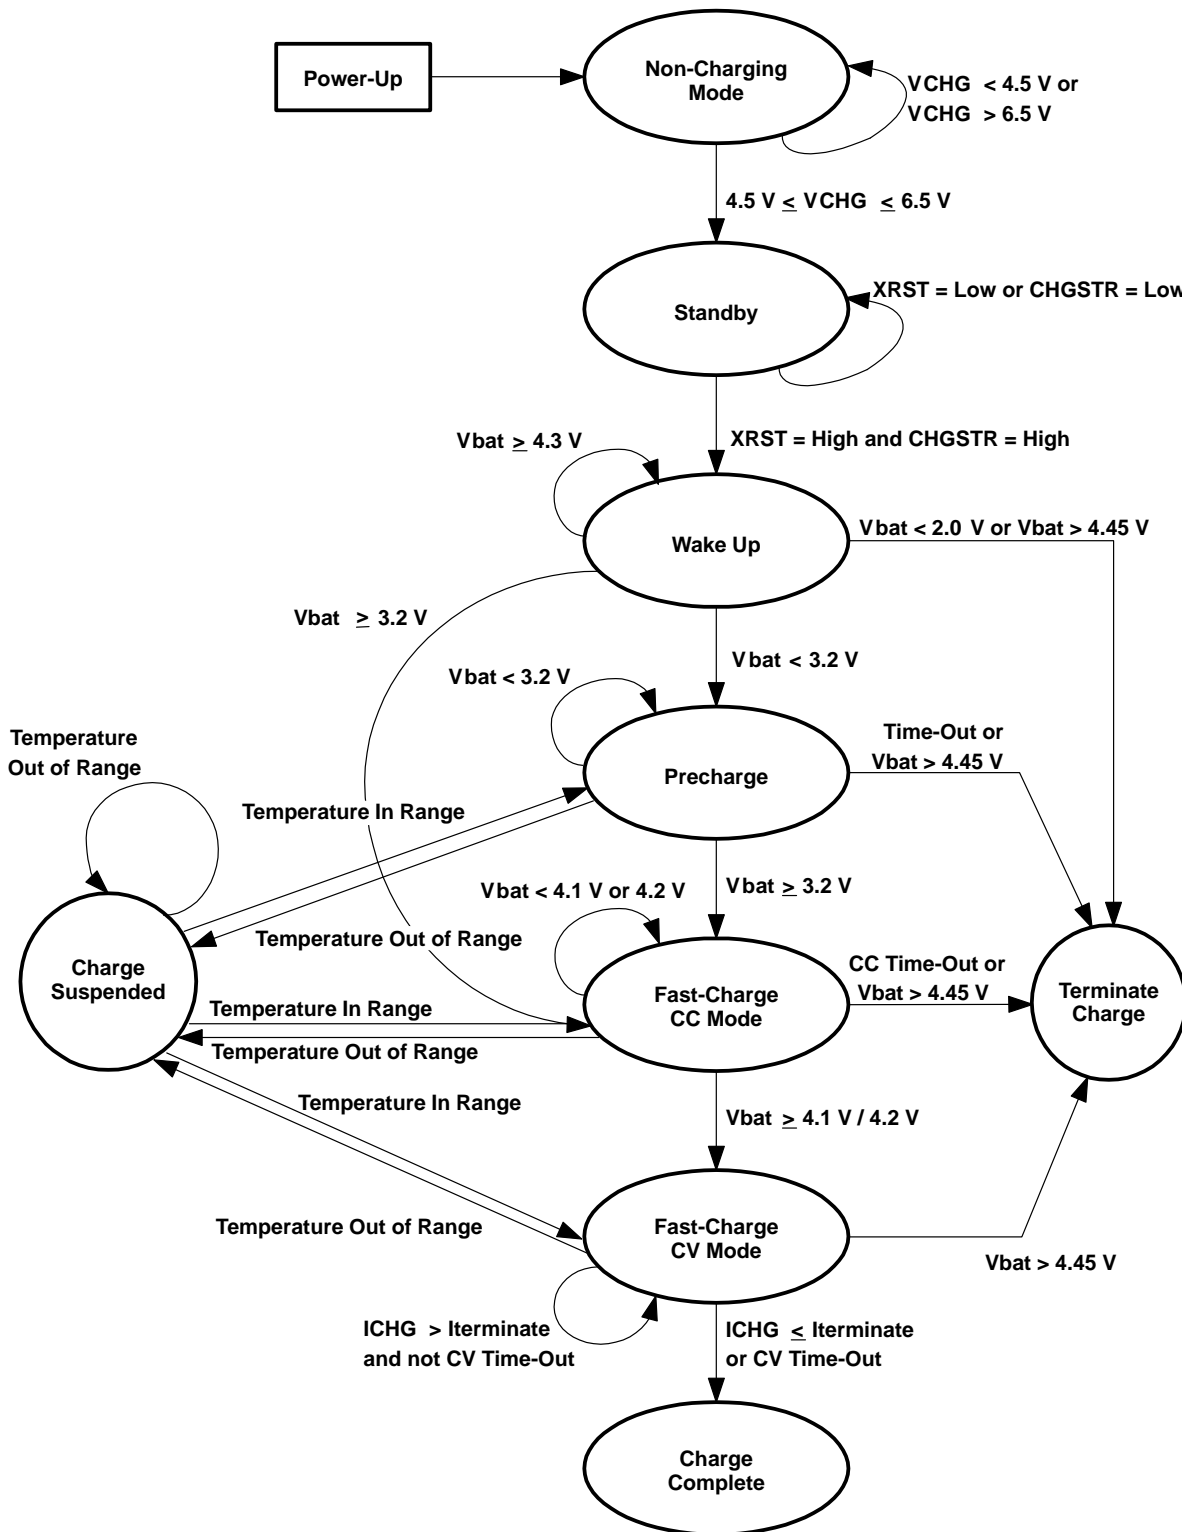

Figure 12. Charger State Diagram

# TWL2213CA POWER SUPPLY MANAGEMENT IC AND Li-Ion BATTERY CHARGE CONTROL

SLVS280 – MARCH 2001

## APPLICATION INFORMATION

### control register—FCR1 (1BH)

BIT	NAME	DESCRIPTION
7	CHGSTR	Set this bit to 1 to start the charger operation. This bit is cleared if the charger is terminated. (Refer to status register table below for terminated conditions)
6	ADC ENABLE	Set this bit to 1 to enable ADC operation, 0 to stop.
5	ADC Function	Set this bit to 1 to have ADC operate continuously. Set to 0 to have ADC to operate one cycle only.
4	ADBv	Set this bit to 1 to enable the VBAT input channel to ADC. 0: disable.
3	VTS	Set this bit to 1 to enable the VTS input channel to ADC. 0: disable.
2	ADCIN1	Set this bit to 1 to enable the ADCIN1 input channel.
1	ADCIN2	Set this bit to 1 to enable the ADCIN2 input channel.
0	IRQ	Status of IRQ pin (refer to IRQ operation section).

ADC has four input channels (ADBv, VTS, ADCIN1, ADCIN2). Each channel can be enabled or disabled individually. The selected channel must be enabled before ADC FUNCTION and ADC ENABLE bits are enabled, the channel is included in the ADC operation.

### IRQ control/status

TWL2213 uses the IRQ signal to inform the external controller about the exception condition of the VCHG input and the charger status. Bit0 reflects the state of the IRQ signal. IRQ occurs in the following five conditions:

1. VCHG returns to operating range from non\_operating range.
2. VCHG goes out of range from operating range.
3. Battery error—occurs only during the charging cycle.
4. Battery temperature out of range—occurs only during the charging cycle. The charger is suspended temporarily. IRQ is cleared when the temperature returns to normal and the charger resumes automatically.
5. Charge complete.

The controller must clear the IRQ signal by writing 0 to Bit0 in the interrupt service routine, except in the VBOT condition. The controller may miss the next interrupt if it fails to write the 0. In VBOT condition, TWL2213 clears the IRQ when the condition goes away.

### status register description—SR (1CH)

SR shows the status of the charger. The external controller reads the SR to track the state of the charging condition.

**TWL2213CA**  
**POWER SUPPLY MANAGEMENT IC AND**  
**Li-Ion BATTERY CHARGE CONTROL**

SLVS280 – MARCH 2001

BIT	NAME	DESCRIPTION
7	VEXT	When Vext = 1 the VCHG input is in the operating range. Otherwise the VCHG is out of range.
6	BATERR	This bit is set to 1 indicating battery error. Four cases cause battery error: pre-charge timeout, constant-current mode timeout, VBAT < 2.9 V, or VBAT > 4.45 V.
5	VBOT	During the charging cycle, if the battery temperature exceeds or falls below the nominal range, this sets to 1. The charger is suspended temporarily. VBOT is cleared when the temperature returns to nominal range and the charger function resumes automatically.
4	CTERM	The charger is terminated normally because the charging current is below the preset termination current value.
3	NOCHG	No charge condition. This condition is detected only during the wake_up state of the charging function. After the 8-second wake up period expires, if VBAT is above 4.3 V, the NOCHG flag is set. The cause of this is a missing or completely charged battery. The TWL2213 does not deactivate the charger by setting CHGSTR = 0. The external processor must turn off the CHGSTR by setting it to 0.
2	PCHG	Set to 1 to indicate the charger is in pre-charge state.
1	CCTO	Set to 1 to indicate the charging time has exceeded the time limit allowed during CC-mode. This is a fatal error. TWL2213 clears CHGSTR bit, sets the BATERR flag, and makes IRQ go high to interrupt the external controller.
0	TCTO	Set to 1 to indicate the charging time has exceeded the overall time limit allowed during CV-mode. This is treated as normal termination of the charger function. TWL2213 clears the CHGSTR bit and sets IRQ to 1 to interrupt the external controller.

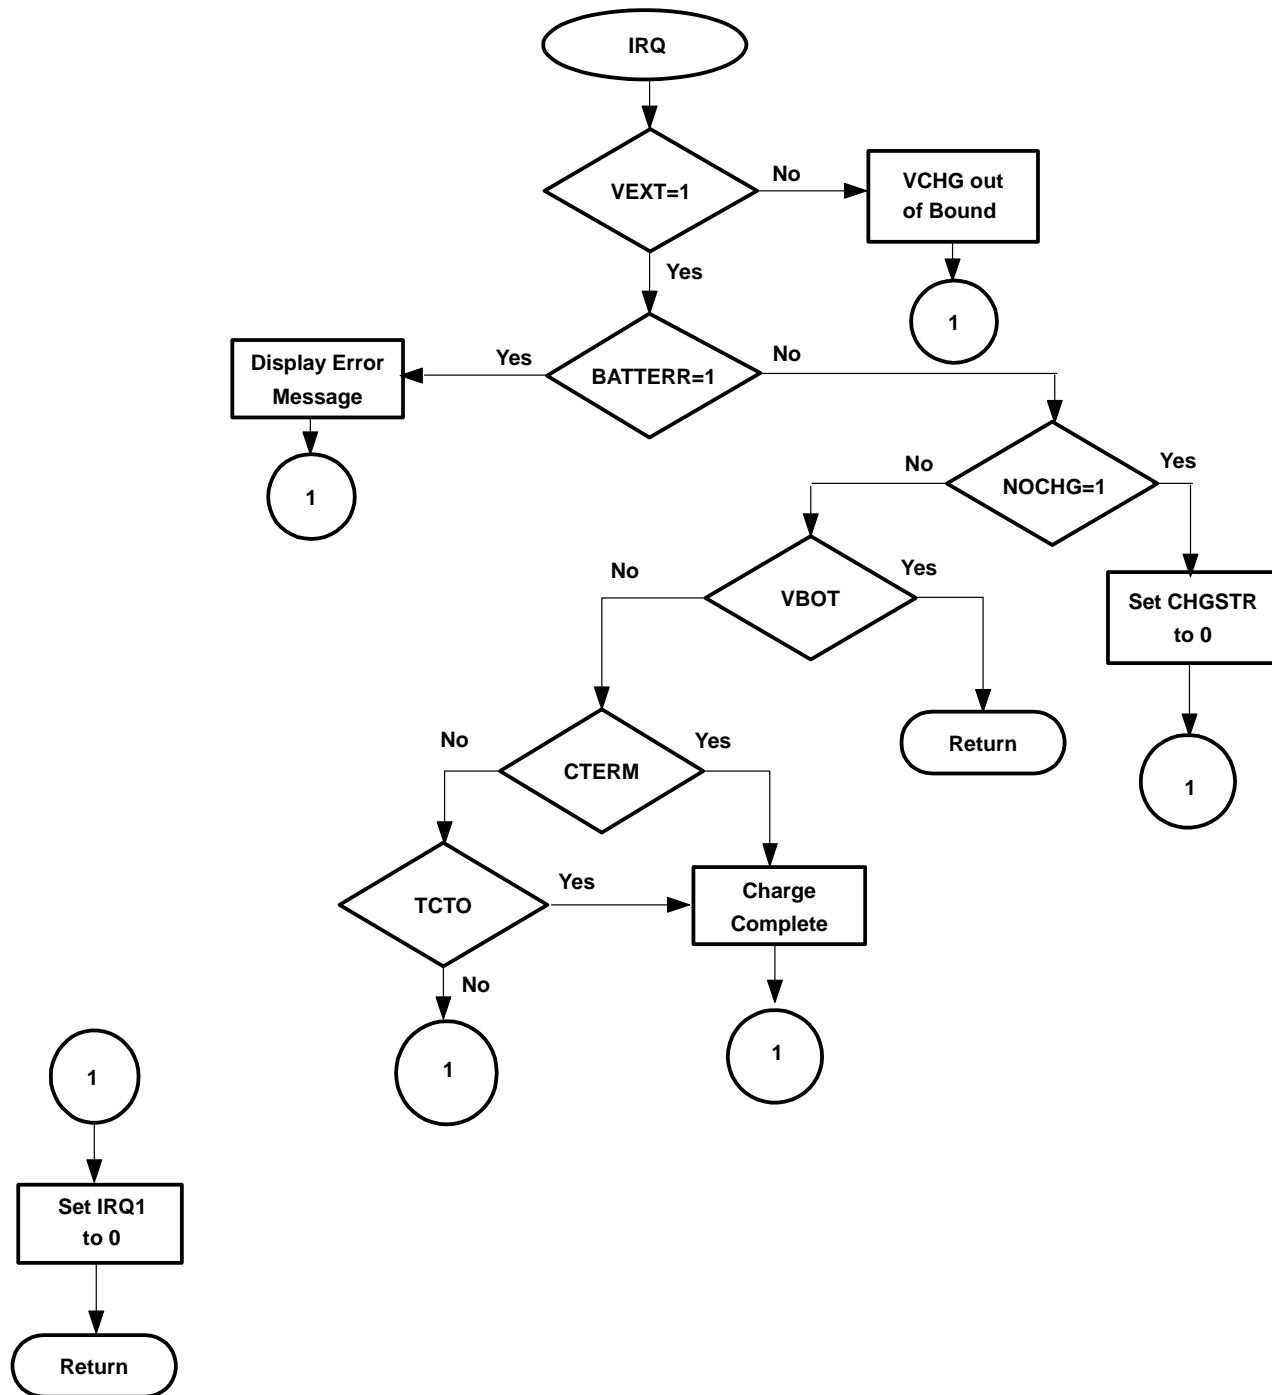

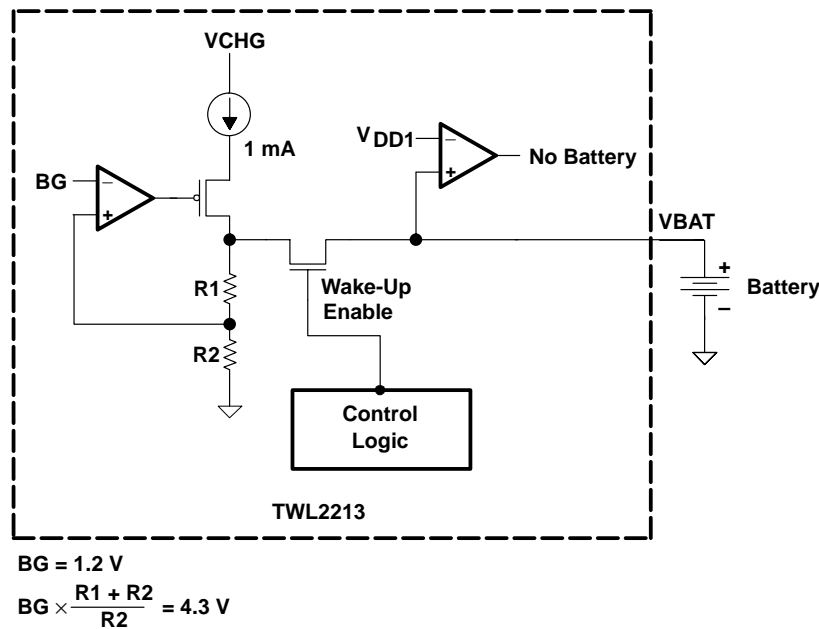

Figure 13. Charger State Diagram

### battery pack wake up

Li-Ion cells can be easily damaged by overcharging or overdischarging. To prevent damage, a pack-protector device is used within the battery pack. During the charging cycle, if the pack-protector senses an over-voltage condition, it disconnects the pack from the charger to prevent further charging but allows discharging. During the discharging cycle, if the protector senses an under-voltage condition, it disconnects the cell from the load to prevent further discharging.

This phase of the charging cycle provides wake-up capability for the battery pack with a pack-protector device. At the start of the charge cycle, the TWL2213 device provides a wake-up signal of 1 mA and 4.3 V to the battery pack. At the end of the 8-second time limit, if the battery pack voltage remains at 4.3 V, a no-battery flag is set in the status register to signal the condition that the charging path is open. If the battery voltage is below 2.5 V, a BATTER flag is set in the status register to signal a bad battery cell. In either case, the charging activity is halted.

**Figure 14. Battery Pack Wake Up**

### precharge

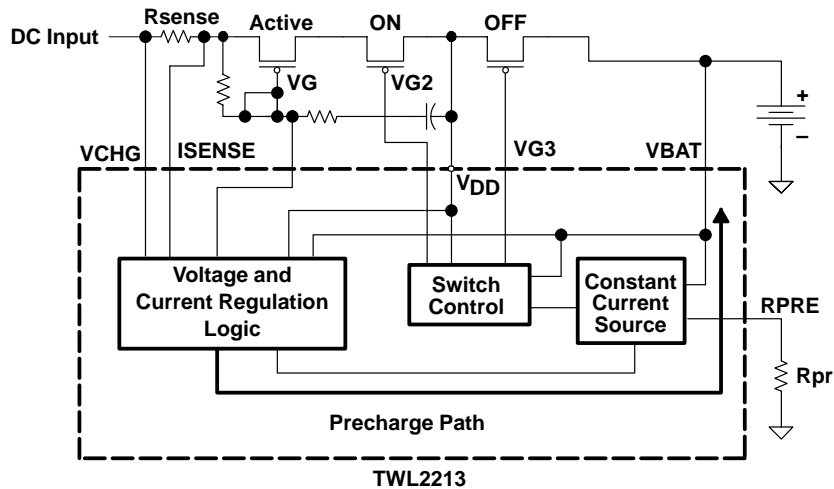

The TWL2213 device starts the precharge phase when the battery voltage is less than 3.2 V. The precharge time is limited by the PTR timer. The precharge current level is set by an external resistor. The maximum precharge current the charger can supply is 100 mA. Use the following equation to choose the external resistor value.

$$R_{pr} = \frac{V_{PRE}}{I_{pre}} \times 45, V_{PRE} = 1.2V \pm 10\%$$

Where:

- R<sub>pr</sub> = External resistor (ohm)
- I<sub>pre</sub> = Desired precharge current (Amp)
- V<sub>PRE</sub> = Voltage at RPRE Pin (Volts)

**APPLICATION INFORMATION**

**Figure 15. Precharge Functional Diagram**

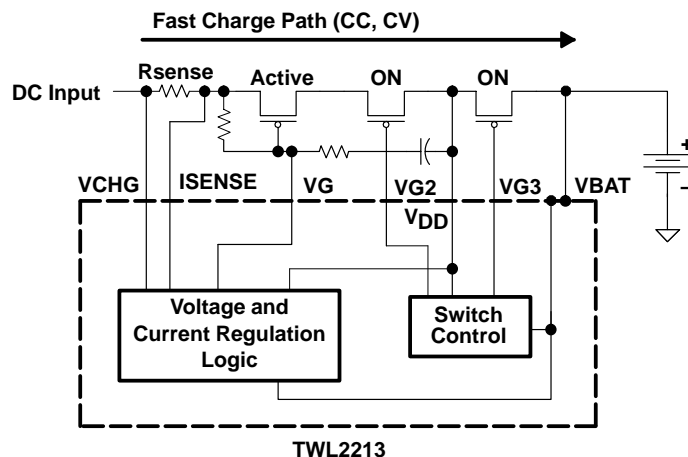

**fast charge constant current (CC mode)**

When the battery voltage is 3.2 V or higher, the TWL2213 device starts the fast charge CC mode cycle. In CC mode, the charger regulates the charging current to its maximum level. The maximum charging current ( $I_{max}$ ) is determined by the external sense resistor,  $R_{sense}$ , and the voltage,  $V_{sense}$ .  $V_{sense}$  is programmable through the I<sup>2</sup>C interface (refer to CSV register for programming information). The range of  $V_{sense}$  is from 100 mV to 200 mV, in 20-mV steps. The CC mode charge time is limited by the CCTR timer.

$$I_{max} = \frac{V_{sense}}{R_{sense}}$$

**fast charge constant current (CV mode)**

When the cell reaches the constant voltage phase, the charger switches to the fast charge CV mode. The charging current begins tapering down while the charging voltage is regulated at the programmed voltage level (4.1 V or 4.2 V). The CV mode charging is limited by the TCTR timer.

**Figure 16. Fast Charge Functional Diagram**

## APPLICATION INFORMATION

### current termination

During the CV mode, the charge cycle is terminated when the charging current is under the programmed terminated level or when the total charge timer (TCTR) times out. The terminated current level can be programmed to 10%, 20%, 30%, 40%, or 50% of the charging current at CC mode.

### temperature monitoring

The TWL2213 device monitors the battery temperature throughout the charge cycle. The input for ADC reference voltage is generated by a negative temperature coefficient (NTC) thermistor. The TWL2213 device compares the ADC input reference voltage to the programmed threshold voltages to determine if charging is allowed. Three required thresholds are:

- VBOTRH+ Voltage for over-temperature cutoff; charging is suspended.
- VBORTH– Voltage to resume charging function for over-temperature cutoff.
- VBORTL Voltage for low-temperature cutoff; charging is suspended.

**Figure 17. Temperature Monitoring**

NOTE: The power-up default values are zero for these three thresholds. If the user opts not to use the temperature monitoring function during the charge cycle, the TS pin of the IC must be tied to the GND to avoid an error signal.

# TWL2213CA POWER SUPPLY MANAGEMENT IC AND Li-Ion BATTERY CHARGE CONTROL

SLVS280 – MARCH 2001

---

## maximum time out

The TWL2213 device provides three timers for maximal time allowed for charging. The time is programmable through I<sup>2</sup>C interface.

TIMER	RANGE	STEP	COMMENT
Precharge timer (PTR)	0–136 min	4 min	During the precharge cycle, if the timer expires before the precharging activity is complete, a BATT_ERR flag is set in the status register, and the charge is terminated.
CC charge timer (CCTR)	0–274 min	8 min	During the CC mode cycle, if the timer expires before the CC activity is complete, a BATT_ERR flag is set in the status register, and the charge is terminated.
Total charge timer (TCTR)	0–15 hr	1 hr	Total charge time is defined as the total charge time of CC mode and CV mode. TCTR time-out occurs only in the CV mode. If the timer expires before, the charge is complete.
