

### FEATURES

- Input-to-output response:** <100 ns
- High input common-mode voltage range**
  - Operating:** 5 V to 65 V
  - Survival:** 0 V to 68 V
- Current output**
- Hysteresis:** 10 mV
- Integrated 2.4 V regulator**
- Wide operating temperature range:** -40°C to +125°C
- 8-lead MSOP package**

### APPLICATIONS

- Overcurrent protection**
  - Motor controls
  - Transmission controls
  - Diesel injection controls
  - DC-to-DC converters
  - Power supplies
  - Batteries

### GENERAL DESCRIPTION

The AD8214 is a fast, high common-mode voltage threshold detector, which operates with a single supply of 5 V to 65 V. Internally the AD8214 features a fast comparator that is optimized for high side operation. It also includes a stable 2.4 V series regulator, which is referenced with respect to the supply voltage. The purpose of the regulator is to provide power to the internal electronics, and set an input comparison threshold below the supply voltage. The inputs of the AD8214 may be operated at, slightly above, or below the power supply. The differential voltage range between the inputs of the AD8214 is 500 mV.

The device features a current output. This current is <100 nA when -IN > +IN and 1 mA when +IN > -IN. The input

### FUNCTIONAL BLOCK DIAGRAM

Figure 1.

voltages are referenced to the supply voltage, as is the internal 2.4 V regulator. The input-to-output response time is typically <100 ns.

As the output switches from low to high, a small hysteresis (10 mV) is activated to minimize the effects of noise in the system, and prevent any false state conditions.

The AD8214 is available in an 8-lead MSOP package. The operating temperature range is -40°C to +125°C, making it ideal for industrial, consumer, and automotive applications.

## SPECIFICATIONS

$V_S = 13.5\text{ V}$ , unless otherwise noted.

**Table 1.**

Parameter	Conditions/Comments	Min	Typ	Max	Unit
VOLTAGE OFFSET					
Offset Voltage (RTI)	$T_A = 25^\circ\text{C}$ , voltage at $-IN$ decreasing		$\pm 1$	$\pm 3$	mV
Over Temperature (RTI)			$\pm 2.5$		mV
Offset Drift				15	
HYSTERESIS	$T_A = 25^\circ\text{C}$ , voltage at $-IN$ increasing	8	10	12	mV
INPUT					
Input Impedance	$V_S = 5\text{ V to }65\text{ V}$		2		$\text{M}\Omega$
Differential				5	
Common Mode					
Voltage Range	Maximum voltage between $+IN$ and $-IN$			500	mV
Differential				$V_S + 0.2$	V
Common Mode		$V_S - 0.9$			
Input Bias Current	$+IN$ or $-IN$		12	20	nA
OUTPUT					
Output Current	$R_{OUT} = 3.3\text{ k}\Omega$ , output high	0.8	1	1.2	mA
	$R_{OUT} = 3.3\text{ k}\Omega$ , output low		100		nA
Rise Time	20% to 80%, $R_{OUT} = 3.3\text{ k}\Omega$ , $V_{OD} = 5\text{ mV}$ , 50 mV step		90		ns
	20% to 80%, $R_{OUT} = 3.3\text{ k}\Omega$ , $V_{OD} > 20\text{ mV}$ , 50 mV step		75		ns
Fall Time	20% to 80%, $R_{OUT} = 3.3\text{ k}\Omega$ , $V_{OD} = 5\text{ mV}$ , 50 mV step		110		ns
	20% to 80%, $R_{OUT} = 3.3\text{ k}\Omega$ , $V_{OD} > 10\text{ mV}$ , 50 mV step		100		ns
REGULATOR					
Nominal Value	$T_A = 25^\circ\text{C}$ , voltage from $V_{REG}$ to $V_S$		2.43		V
	$T_A = -40^\circ\text{C to }+125^\circ\text{C}$		$\pm 5$		%
DYNAMIC RESPONSE					
Propagation Delay <sup>1</sup>	50 mV to 250 mV step				
	$5\text{ mV} \leq V_{OD} \leq 15\text{ mV}$ , output low to high		90		ns
	$15\text{ mV} \leq V_{OD} \leq 30\text{ mV}$ , output low to high		80		ns
	$V_{OD} \geq 30\text{ mV}$ , output low to high		75		ns
INPUT-REFERRED DYNAMIC ERROR <sup>2</sup>			15		mV
POWER SUPPLY					
Operating Range					
Maximum Voltage	GND to $V_S$			65	V
Minimum Voltage	GND to $V_S$	5			V
Output Voltage Range <sup>3</sup>	With respect to $V_{REG}$	2		62.5	V
Supply Current	Output low		240		$\mu\text{A}$
	Output high		1.2		mA
TEMPERATURE RANGE FOR SPECIFIED PERFORMANCE		-40		+125	$^\circ\text{C}$

<sup>1</sup>  $V_{OD}$  represents the overdrive voltage, or the amount of voltage by which the threshold point has been exceeded.

<sup>2</sup> See the Input-Referred Dynamic Error section.

<sup>3</sup> The voltage at OUT must not be allowed to exceed the  $V_{REG}$  voltage, which is always 2.4 V less than the supply. For example, when the supply voltage is 5 V and the output current is 1 mA, the load resistor must not be more than  $(5\text{ V} - 2.4\text{ V}) / (1\text{ mA} \times (1 + 20\%))$ , or 2.17 k $\Omega$ , to ensure the signal does not exceed 2.6 V. As the supply increases, the output signal also can be increased, by the same amount.

## ABSOLUTE MAXIMUM RATINGS

$T_A = -40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$

Table 2.

Parameter	Rating
Supply Voltage	65 V
Continuous Input Voltage	68 V
Reverse Supply Voltage	0.3 V
Operating Temperature Range	$-40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$
Storage Temperature Range	$-65^{\circ}\text{C}$ to $+150^{\circ}\text{C}$
Output Short-Circuit Duration	Indefinite

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

## THEORY OF OPERATION

The AD8214 is a high voltage comparator offering an input-to-output response time of less than 100 ns. This device is ideal for detecting overcurrent conditions on the high side of the control loop. The AD8214 is designed specifically to facilitate and allow for fast shutdown of the control loop, preventing damage due to excessive currents to the FET, load, or shunt resistor.

The AD8214 operates with a supply of 5 V to 65 V. It combines a fast comparator, optimized for high side operation, with a 2.4 V series voltage regulator. The regulator provides a stable voltage that is negative with respect to the positive supply rail, and it is intended to provide power to the internal electronics, set a comparison threshold below the supply rail, and power small application circuits used with the comparator.

The differential input of the comparator may be operated at, or slightly above or below, the positive supply rail. Typically, one of the comparator inputs is driven negative with respect to the positive supply by a small series resistor carrying the main supply current to the load. The other input of the comparator

connects to a voltage divider across the regulator, so the comparator trips as the voltage across the series resistor crosses the user-selected threshold.

The AD8214 features a current output. The current is low (100 nA typical), until the user selected threshold is crossed. After this point the output switches to high (1 mA typical). The current output driver complies with load voltage from 0 V to  $(V_s - 2.4 \text{ V})$ . The current easily drives a ground referenced resistor to develop logic levels determined by the value of the load resistor.

The comparator input is balanced to switch as the inverting input ( $-IN$ ) is driven negative with respect to the noninverting input ( $+IN$ ). As the comparator output switches from 0 mA to 1 mA, a small hysteresis (10 mV) is activated to minimize the effects of noise in the system that may be triggered by the comparator signal. This means that to restore the output to zero, the input polarity must be reversed by 10 mV beyond the original threshold.

Figure 28. Simplified Schematic

## COMPARATOR OFFSET AND HYSTERESIS

The AD8214 features built-in hysteresis to minimize the effects of noise in the system. There is also a small offset at the input of the device.

Figure 29. Hysteresis and Input Offset Voltage Definition

Figure 29 shows the relationship between the input voltage and the output current. The horizontal axis represents the voltage between the positive (+IN) and negative (-IN) inputs of the AD8214. The vertical axis shows the output current for a given input voltage.

$V_{TH}$  represents the point where the inputs are at the same voltage level (+IN = -IN). The output of the AD8214 remains low ( $V_{OL}$ ) provided (-IN) is at a higher voltage potential than (+IN). As the input voltage transitions to +IN > -IN, the output switches states. Under ideal conditions, the output is expected to change states at exactly  $V_{TH}$ . In practice, the output switches when the inputs are equal  $\pm$  a small offset voltage ( $V_{OS}$ ).

Once the output switches from low to high, it remains in this state until the input voltage falls below the hysteresis voltage. Typically, this occurs when +IN is 10 mV below -IN.

## SETTING THE INPUT THRESHOLD VOLTAGE

The AD8214 features a 2.4 V series regulator, which can be used to set a reference threshold voltage with two external resistors. The resistors constitute a voltage divider, the middle point of which connects to +IN. The total voltage across the resistors is always 2.4 V. (See Figure 28 for proper resistor placement.) The

values for these resistors can be chosen based on the desired threshold voltage using the equation:

$$\left(\frac{2.4}{R1+R2}\right) \times R1 = V_{TH(+IN)} \quad (1)$$

For proper operation it is recommended that the internal 2.4 V regulator not be loaded down by using small R1 and R2 values. Figure 11 shows the proper range for the total series resistance.

## INPUT-REFERRED DYNAMIC ERROR

Frequently, the dynamics of comparators are specified in terms of propagation delay of the response at the output to an input pulse crossing the threshold between two overload states. For this measurement, the rise time of the input pulse is negligible compared to the comparator propagation delay. In the case of the AD8214, this propagation delay is typically 100 ns, when the input signal is a fast step.

The primary purpose of the AD8214 is to monitor for over-current conditions in a system. It is much more common that in such systems, the current in the path increases slowly; therefore, the transition between two input overload conditions around the threshold is slow relative to the propagation delay. In some cases, this transition can be so slow that the time from the actual threshold crossing to the output signal switching states is longer than the specified propagation delay, due to the comparator dynamics.

If the voltage at the input of the AD8214 is crossing the set threshold at a rate  $\leq 100$  mV/ $\mu$ s, the output switches states before the threshold voltage has been exceeded by 15 mV.

Therefore, if the input signal is changing so slowly that the propagation delay is affected, the error that accumulates at the input while waiting for the output response is proportionately smaller and, typically, less than 15 mV for ramp rates  $\leq 100$  mV/ $\mu$ s.

## APPLICATIONS

### TYPICAL SETUP AND CALCULATIONS

The key feature of the AD8214 is its ability to detect an overcurrent condition on the high side of the rail and provide a signal in less than 100 ns. This performance protects expensive loads, FETs, and shunt resistors in a variety of systems and applications. This section details a typical application in which the normal current in the system is less  $\leq 10$  A and an overcurrent detection is necessary when 15 A is detected in the path.

If we assume a shunt resistance ( $R_{SHUNT}$ ) of  $0.005 \Omega$  and a common-mode voltage range of 5 V to 65 V, the typical voltage across the shunt resistor is

$$10 \text{ A} \times 0.005 \Omega = 50 \text{ mV}$$

The voltage drop across the shunt resistor, in the case of an overcurrent condition is

$$15 \text{ A} \times 0.005 \Omega = 75 \text{ mV}$$

The threshold voltage, must therefore be set at 75 mV, corresponding to the overcurrent condition. R1 and R2 can be selected based on this 75 mV threshold at the positive input of the comparator.

A low load current across the regulator corresponds to optimal regulator performance; therefore, the series resistance of R1 and R2 must be relatively large. For this case, the total resistance can be set as

$$R1 + R2 = 200 \text{ k}\Omega$$

To have a 75 mV drop across R1, the following calculations apply:

$$\frac{2.4 \text{ V}}{200 \text{ k}\Omega} = 12 \mu\text{A}$$

$$\frac{75 \text{ mV}}{12 \mu\text{A}} = 6.25 \text{ k}\Omega = R1$$

$$R2 = (200 \text{ k}\Omega - R1) = 193.75 \text{ k}\Omega$$

The values for R1 and R2 are set; correspondingly, the threshold voltage at +IN is set at 75 mV.

Under normal operating conditions, the current is 10 A or less, corresponding to a maximum voltage drop across the shunt of 50 mV. This means that the negative input of the comparator is 50 mV below the battery voltage. Since the positive input is 75 mV below the battery voltage, the negative input is at a higher potential than the positive; therefore, the output of the AD8214 is low.

If the current increases to 15 A, the drop across the shunt is 75 mV. As the current continues to increase, the positive input of the comparator reaches a higher potential than the negative, and the output of the AD8214 switches from low to high. The input-to-output response of the AD8214 is less than 100 ns. The output resistor in this case is selected so that the logic level high signal is 3.3 V.

The output changes states from low to high in the case of an overcurrent condition. However, the input offset voltage is typically 1 mV; therefore, this must be taken into consideration when choosing the threshold voltage. When the current in the system drops back down to normal levels, the AD8214 changes states from high to low. However, due to the built-in 10 mV hysteresis, the voltage at (-IN) must be 10 mV higher than the threshold for the output to change states from high to low. This built-in hysteresis is intended to prevent input chatter as well as any false states.

Table 4 shows typical resistors combinations that can be used to set an input threshold voltage. Numbers are based on a  $2.43 \text{ V } V_{REG}$ .

**Table 4.**

Threshold (mV)	R1 (k $\Omega$ )	R2 (k $\Omega$ )
30	1.5	120
50	1.6	75
60	2	80
75	2.4	75
110	8.06	169

Figure 30. Typical Application

**HIGH SIDE OVERCURRENT DETECTION**

The AD8214 is useful for many automotive applications using the load configuration shown in Figure 31. Because the part powers directly from the battery voltage, the shunt resistor must be on the high side. The AD8214 monitors the current in the path as long as the battery voltage is between 5 V and 65 V. If the current

reaches an undesirable level that corresponds to the user-selected threshold, the output of the AD8214 switches states in less than 100 ns. The microcontroller, analog-to-digital converter, or FET driver can be directly notified of this condition.
