## FEATURES

AD5200-256-Position
AD5201-33-Position
$10 \mathrm{k} \Omega, 50 \mathrm{k} \Omega$
3-Wire SPI-Compatible Serial Data Input
Single Supply 2.7 V to 5.5 V or
Dual Supply $\pm 2.7 \mathrm{~V}$ for AC or Bipolar Operations
Internal Power-On Midscale Preset

## APPLICATIONS

Mechanical Potentiometer Replacement
Instrumentation: Gain, Offset Adjustment Programmable Voltage-to-Current Conversion Programmable Filters, Delays, Time Constants Line Impedance Matching

## GENERAL DESCRIPTION

The AD5200 and AD5201 are programmable resistor devices, with 256 positions and 33 positions respectively, that can be digitally controlled through a 3-wire SPI serial interface. The terms programmable resistor, variable resistor (VR), and RDAC are commonly used interchangeably to refer to digital potentiometers. These devices perform the same electronic adjustment function as a potentiometer or variable resistor. Both AD5200/AD5201 contain a single variable resistor in the compact $\mu$ SOIC-10 package. Each device contains a fixed wiper resistance at the wiper contact that taps the programmable resistance at a point determined by a digital code. The code is loaded in the serial input register. The resistance between the wiper and either end point of the programmable resistor varies linearly with respect to the digital code transferred into the VR latch. Each variable resistor offers a completely programmable value of resistance, between the A terminal and the wiper, or the $B$ terminal and the wiper. The fixed A-to-B terminal resistance of $10 \mathrm{k} \Omega$ or $50 \mathrm{k} \Omega$
has a nominal temperature coefficient of $500 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$. The VR has a VR latch that holds its programmed resistance value. The VR latch is updated from an SPI-compatible serial-to-parallel shift register that is loaded from a standard 3-wire serial-input digital interface. Eight data bits for the AD5200 and six data bits for the AD5201 make up the data word that is clocked into the serial input register. The internal preset forces the wiper to the midscale position by loading $80_{\mathrm{H}}$ and $10_{\mathrm{H}}$ into AD 5200 and AD5201 VR latches respectively. The SHDN pin forces the resistor to an end-to-end open-circuit condition on the A terminal and shorts the wiper to the B terminal, achieving a microwatt power shutdown state. When SHDN is returned to logic high, the previous latch setting puts the wiper in the same resistance setting prior to shutdown. The digital interface is still active during shutdown so that code changes can be made that will produce a new wiper position when the device is returned from shutdown.
All parts are guaranteed to operate over the extended industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

## NOTES

${ }^{1}$ Typicals represent average readings at $25^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$.
${ }^{2}$ Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from ideal between successive tap positions. Parts are guaranteed monotonic. $\mathrm{I}_{\mathrm{W}}=\mathrm{V}_{\mathrm{DD}} / \mathrm{R}$ for both $\mathrm{V}_{\mathrm{DD}}=+2.7 \mathrm{~V}$,
$\mathrm{V}_{\mathrm{SS}}=-2.7 \mathrm{~V}$.
${ }^{3} \mathrm{~V}_{\mathrm{AB}}=\mathrm{V}_{\mathrm{DD}}$, Wiper $\left(\mathrm{V}_{\mathrm{W}}\right)=$ No connect.
${ }^{4} \mathrm{INL}$ and DNL are measured at $\mathrm{V}_{\mathrm{W}}$ with the RDAC configured as a potentiometer divider similar to a voltage output $\mathrm{D} / \mathrm{A}$ converter. $\mathrm{V}_{\mathrm{A}}=\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\mathrm{B}}=0 \mathrm{~V} . \mathrm{DNL}$ specification limits of $\pm 1$ LSB maximum are Guaranteed Monotonic operating conditions.
${ }^{5}$ Resistor Terminals A, B, W have no limitations on polarity with respect to each other.
${ }^{6}$ Guaranteed by design and not subject to production test.
${ }^{7}$ Measured at the A terminal. A terminal is open-circuited in shutdown mode.
${ }^{8} \mathrm{P}_{\text {DISs }}$ is calculated from ( $\mathrm{I}_{\mathrm{DD}} \times \mathrm{V}_{\mathrm{DD}}$ ). CMOS logic level inputs result in minimum power dissipation.
${ }^{9}$ All dynamic characteristics use $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$.
Specifications subject to change without notice.

## NOTES

${ }^{1}$ Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
${ }^{2}$ Max current is bounded by the maximum current handling of the switches, maximum power dissipation of the package, and maximum applied voltage across any two of the A, B, and W terminals at a given resistance. Please refer to TPC 31 and TPC 32 for detail.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD5200/AD5201 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## OPERATION

The AD5200/AD5201 provide 255 and 33 positions digitallycontrolled variable resistor (VR) devices. Changing the programmed VR settings is accomplished by clocking in an 8-bit serial data word for AD5200, and a 6-bit serial data word for AD5201, into the SDI (Serial Data Input) pins. Table I provides the serial register data word format. The AD5200/AD5201 are preset to a midscale internally during power-on condition. In addition, the AD5200/AD5201 contain power shutdown SHDN pins that place the RDAC in a zero power consumption state where the immediate switches next to Terminals A and $B$ are open-circuited. Meanwhile, the wiper W is connected to $B$ terminal, resulting in only leakage current consumption in the VR structure. During shutdown, the VR latch contents are maintained when the RDAC is inactive. When the part is returned from shutdown, the stored VR setting will be applied to the RDAC.

Table I. AD5200 Serial-Data Word Format

*Six data bits are needed for 33 positions.

## PROGRAMMING THE VARIABLE RESISTOR

## Rheostat Operation

The nominal resistance of the RDAC between Terminals A and $B$ are available with values of $10 \mathrm{k} \Omega$ and $50 \mathrm{k} \Omega$. The final two digits of the part number determine the nominal resistance value, e.g., $10 \mathrm{k} \Omega=10$ and $50 \mathrm{k} \Omega=50$. The nominal resistance $\left(\mathrm{R}_{\mathrm{AB}}\right)$ of AD5200 has 256 contact points accessed by the wiper terminal. The 8-bit data word in the RDAC latch of AD5200 is decoded to select one of the 256 possible settings. In both parts, the wiper's first connection starts at the $B$ terminal for data $00_{\mathrm{H}}$. This B-terminal connection has a wiper contact resistance of $50 \Omega$ as long as valid $\mathrm{V}_{\mathrm{DD}} / \mathrm{V}_{\mathrm{SS}}$ is applied, regardless of the nominal resistance. For a $10 \mathrm{k} \Omega$ part, the second connection of AD5200 is the first tap point with $89 \Omega\left[\mathrm{R}_{\mathrm{WB}}=\mathrm{R}_{\mathrm{AB}} / 255+\mathrm{R}_{\mathrm{W}}=39 \Omega+50 \Omega\right]$ for data $01_{\mathrm{H}}$. The third connection is the next tap point representing $78+50=128 \Omega$ for data $02_{\mathrm{H}}$. Due to its unique internal structure, AD5201 has 5-bit +1 resolution, but needs a 6 -bit data word to achieve the full 33 steps resolution. The 6 -bit data word in the RDAC latch is decoded to select one of the 33 possible settings. Data 34 to 63 will automatically be equal to Position 33. The wiper $00_{\mathrm{H}}$ connection of AD5201 gives $50 \Omega$. Similarly, for a $10 \mathrm{k} \Omega$ part, the first tap point of AD5201 yields $363 \Omega$ for data $01_{\mathrm{H}}, 675 \Omega$ for data $02_{\mathrm{H}}$. For both AD5200 and AD5201, each LSB data value increase moves the wiper up the resistor ladder until the last tap point is reached. Figures $2 a$ and $2 b$ show the simplified diagrams of the equivalent RDAC circuits.

Figure 2a. AD5200 Equivalent RDAC Circuit. 255 positions can be achieved up to Switch $S W_{2}{ }^{N}{ }_{-1}$.

Figure 2b. AD5201 Equivalent RDAC Circuit. Unlike AD5200, 33 positions can be achieved all the way to Switch SW ${ }_{2}{ }^{N}$.
The general equation determining the digitally programmed output resistance between W and B is:

$$
\begin{array}{ll}
R_{W B}(D)=\frac{D}{255} R_{A B}+50 \Omega & \text { for AD5200 } \\
R_{W B}(D)=\frac{D}{32} R_{A B}+50 \Omega & \text { for AD5201 } \tag{2}
\end{array}
$$

where:
$D$ is the decimal equivalent of the data contained in RDAC latch.
$R_{A B}$ is the nominal end-to-end resistance.
$R_{W}$ is the wiper resistance contributed by the on-resistance of the internal switch.

Note $D$ in AD5200 is between 0 to 255 for 256 positions. On the other hand, $D$ in AD 5201 is between 0 to 32 so that 33 positions can be achieved due to the slight internal structure difference, Figure 2b.
Again if $R_{A B}=10 \mathrm{k} \Omega$ and A terminal can be opened or tied to W , the following output resistance between W to B will be set for the following RDAC latch codes:

AD5200 Wiper-to-B Resistance

| $\mathbf{D}$ <br> (DEC) | $\mathbf{R}_{\mathrm{WB}}$ <br> $(\boldsymbol{\Omega})$ | Output State |
| :--- | :--- | :--- |
| 255 | 10050 | Full-Scale $\left(\mathrm{R}_{\mathrm{AB}}+\mathrm{R}_{\mathrm{W}}\right)$ |
| 128 | 5070 | Midscale |
| 1 | 89 | 1 LSB |
| 0 | 50 | Zero-Scale (Wiper Contact Resistance) |

AD5201 Wiper-to-B Resistance

| $\mathbf{D}$ <br> $(\mathbf{D E C})$ | $\mathbf{R}_{\mathbf{W B}}$ <br> $(\boldsymbol{\Omega})$ | Output State |
| :--- | :--- | :--- |
| 32 | 10050 | Full-Scale $\left(\mathrm{R}_{\mathrm{AB}}+\mathrm{R}_{\mathrm{W}}\right)$ |
| 16 | 5050 | Midscale |
| 1 | 363 | 1 LSB |
| 0 | 50 | Zero-Scale (Wiper Contact Resistance) |

Note that in the zero-scale condition a finite wiper resistance of $50 \Omega$ is present. Care should be taken to limit the current flow between $W$ and $B$ in this state to no more than $\pm 20 \mathrm{~mA}$ to avoid degradation or possible destruction of the internal switch contact.
Like the mechanical potentiometer the RDAC replaces, it is totally symmetrical. The resistance between the wiper $W$ and Terminal A also produces a digitally controlled resistance $\mathrm{R}_{\mathrm{WA}}$. When these terminals are used, the B terminal should be tied to the wiper. Setting the resistance value for $\mathrm{R}_{\mathrm{WA}}$ starts at a maximum value of resistance and decreases as the data loaded in the latch is increased in value. The general equation for this operation is:

$$
\begin{equation*}
R_{W A}(D)=\frac{(255-D)}{255} R_{A B}+50 \Omega \quad \text { for AD5200 } \tag{3}
\end{equation*}
$$

$$
\begin{equation*}
R_{W A}(D)=\frac{(32-D)}{32} R_{A B}+50 \Omega \quad \text { for AD5201 } \tag{4}
\end{equation*}
$$

Similarly, $D$ in AD5200 is between 0 to 255, whereas D in AD5201 is between 0 to 32 .
For $\mathrm{R}_{\mathrm{AB}}=10 \mathrm{k} \Omega$ and B terminal is opened or tied to the wiper W , the following output resistance between W and A will be set for the following RDAC latch codes:

AD5200 Wiper-to-A Resistance

| D <br> (DEC) | $\mathbf{R}_{\text {WA }}$ <br> $(\boldsymbol{\Omega})$ | Output State |
| :--- | :--- | :--- |
| 255 | 50 | Full-Scale $\left(R_{W}\right)$ |
| 128 | 5030 | Midscale |
| 1 | 10011 | 1 LSB |
| 0 | 10050 | Zero-Scale $\left(R_{A B}+R_{W}\right)$ |

AD5201 Wiper-to-A Resistance

| D <br> (DEC) | $\mathbf{R}_{\text {WA }}$ <br> $(\boldsymbol{\Omega})$ | Output State |
| :--- | :--- | :--- |
| 32 | 50 | Full-Scale $\left(R_{W}\right)$ |
| 16 | 5050 | Midscale |
| 1 | 9738 | 1 LSB |
| 0 | 10050 | Zero-Scale $\left(R_{A B}+R_{W}\right)$ |

The tolerance of the nominal resistance can be $\pm 30 \%$ due to process lot dependance. If users apply the RDAC in rheostat (variable resistance) mode, they should be aware of such specification of tolerance. The change in $\mathrm{R}_{\mathrm{AB}}$ with temperature has a $500 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ temperature coefficient.

## PROGRAMMING THE POTENTIOMETER DIVIDER

## Voltage Output Operation

The digital potentiometer easily generates output voltages at wiper-to-B and wiper-to-A to be proportional to the input voltage at A to B .
Unlike the polarity of $\mathrm{V}_{\mathrm{DD}}-\mathrm{V}_{\mathrm{SS}}$, which must be positive, voltage across $\mathrm{A}-\mathrm{B}, \mathrm{W}-\mathrm{A}$, and $\mathrm{W}-\mathrm{B}$ can be at either polarity.
If ignoring the effects of the wiper resistance for an approximation, connecting A terminal to 5 V and B terminal to ground produces an output voltage at the wiper which can be any value starting at almost zero to almost full scale with the minor deviation contributed by the wiper resistance. Each LSB of voltage is equal to the voltage applied across Terminal AB divided by the $2^{\mathrm{N}}-1$ and $2^{\mathrm{N}}$ position resolution of the potentiometer divider for AD5200 and AD5201 respectively. The general equation defining the output voltage with respect to ground for any valid input voltage applied to Terminals A and B is:

$$
\begin{array}{ll}
V_{W}(D)=\frac{D}{255} V_{A B}+V_{B} & \text { for AD5200 } \\
V_{W}(D)=\frac{D}{32} V_{A B}+V_{B} & \text { for AD5201 } \tag{6}
\end{array}
$$

where $D$ in AD5200 is between 0 to 255 and $D$ in AD5201 is between 0 to 32 .

For more accurate calculation, including the effects of wiper resistance, $\mathrm{V}_{\mathrm{W}}$ can be found as:

$$
\begin{equation*}
V_{W}(D)=\frac{R_{W B}(D)}{R_{A B}} V_{A}+\frac{R_{W A}(D)}{R_{A B}} V_{B} \tag{7}
\end{equation*}
$$

where $R_{W B}(D)$ and $R_{W A}(D)$ can be obtained from Equations 1 to 4 .

Operation of the digital potentiometer in the divider mode results in more accurate operation over temperature. Here the output voltage is dependent on the ratio of the internal resistors and not the absolute values; therefore, the drift reduces to $15 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$.

## DIGITAL INTERFACING

The AD5200/AD5201 contain a standard three-wire serial input control interface. The three inputs are clock (CLK), $\overline{\mathrm{CS}}$, and serial data input (SDI). The positive-edge-sensitive CLK input requires clean transitions to avoid clocking incorrect data into the serial input register. Standard logic families work well. If mechanical switches are used for product evaluation, they should be debounced by a flip-flop or other suitable means. Figure 3 shows more detail of the internal digital circuitry. When $\overline{\mathrm{CS}}$ is low, the clock loads data into the serial register on each positive clock edge (see Table III).

Figure 3. Block Diagram
Table III. Input Logic Control Truth Table

| CLK | $\overline{\mathrm{CS}}$ | SHDN | Register Activity |
| :---: | :---: | :---: | :---: |
| L | L | H | No SR effect. |
| P | L | H | Shift one bit in from the SDI pin. |
| X | P | H | Load SR data into RDAC latch. |
| X | H | H | No operation. |
| X | H | L | Open circuit on A terminal and short circuit between W to B terminals. |
| NOTE |  |  |  |

All digital inputs are protected with a series input resistor and parallel Zener ESD structure shown in Figure 4. Applies to digital input pins $\overline{\mathrm{CS}}, \mathrm{SDI}, \overline{\mathrm{SHDN}}, \mathrm{CLK}$.

[^0]:    NOTES
    ${ }^{1}$ Typicals represent average readings at $25^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$.
    ${ }^{2}$ Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from ideal between successive tap positions. Parts are guaranteed monotonic. $\mathrm{I}_{\mathrm{w}}=\mathrm{V}_{\mathrm{DD}} / \mathrm{R}$ for both $\mathrm{V}_{\mathrm{DD}}=+2.7 \mathrm{~V}$, $\mathrm{V}_{\mathrm{SS}}=-2.7 \mathrm{~V}$.
    ${ }^{3} \mathrm{~V}_{\mathrm{AB}}=\mathrm{V}_{\mathrm{DD}}$, Wiper $\left(\mathrm{V}_{\mathrm{W}}\right)=$ No connect.
    ${ }^{4}$ Six bits are needed for 33 positions even though it is not a 64 -position device.
    ${ }^{5} \mathrm{INL}$ and DNL are measured at $\mathrm{V}_{\mathrm{W}}$ with the RDAC configured as a potentiometer divider similar to a voltage output $\mathrm{D} / \mathrm{A}$ converter. $\mathrm{V}_{\mathrm{A}}=\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\mathrm{B}}=0 \mathrm{~V} . \mathrm{DNL}$ specification limits of $\pm 1$ LSB maximum are Guaranteed Monotonic operating conditions.
    ${ }^{6}$ Resistor Terminals A, B, W have no limitations on polarity with respect to each other.
    ${ }^{7}$ Guaranteed by design and not subject to production test.
    ${ }^{8}$ Measured at the A terminal. A terminal is open-circuited in shutdown mode.
    ${ }^{9} P_{\text {DISS }}$ is calculated from ( $I_{D D} \times V_{D D}$ ). CMOS logic level inputs result in minimum power dissipation.
    ${ }^{10}$ All dynamic characteristics use $V_{D D}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$.
    Specifications subject to change without notice.
