Quad, Current-Output, Serial-Input 16-/14-Bit DACs

AD5544/AD5554

FEATURES

AD5544 16-bit resolution
AD5554 14-bit resolution
2 mA full-scale current ±20%, with V_{REF} = ±10 V
2 µs settling time
V_{SS} BIAS for zero-scale error reduction @ temp
midscale or zero-scale reset
Four separate, 4-Q multiplying reference inputs
SPI®-compatible 3-wire interface
Double buffered registers enable
Simultaneous multichannel change
Internal power ON reset
Compact SSOP-28 package

APPLICATIONS

Automatic test equipment
Instrumentation
Digitally controlled calibration

FUNCTIONAL BLOCK DIAGRAM

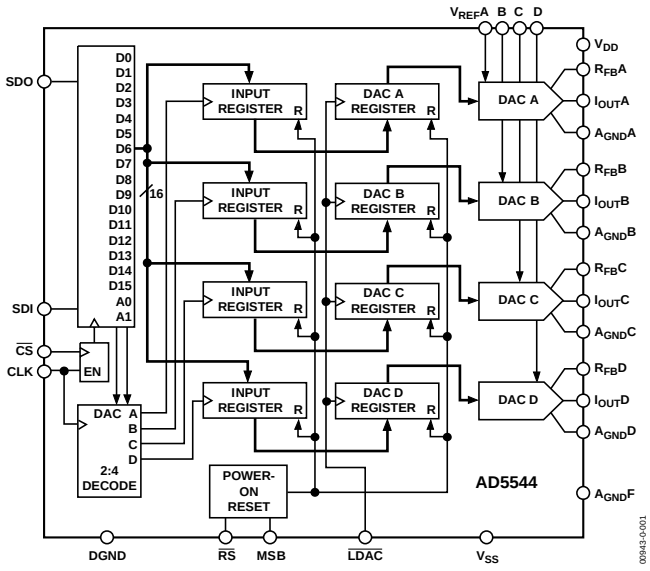

Figure 1.

GENERAL DESCRIPTION

The AD5544/AD5554 quad, 16-/14-bit, current-output, digital to-analog converters are designed to operate from a single 5 V supply.

The applied external reference input voltage (V_{REF}) determines the full-scale output current. Integrated feedback resistors (R_{FB}) provide temperature-tracking, full-scale voltage outputs when combined with an external I-to-V precision amplifier.

A double-buffered serial-data interface offers high speed, 3-wire, SPI- and microcontroller-compatible inputs using serial-data-in (SDI), a chip-select ($\overline{CS}$), and clock (CLK) signals. In addition, a serial-data-out pin (SDO) allows for daisy-chaining when multiple packages are used. A common, level-sensitive, load-DAC strobe ($\overline{LDAC}$) input allows the simultaneous update of all DAC outputs from previously loaded input registers. Additionally, an internal power ON reset forces the output voltage to zero at system turn ON. An MSB pin allows system reset assertion ($\overline{RS}$) to force all registers to zero code when MSB = 0, or to half-scale code when MSB = 1.

The AD5544/AD5554 are packaged in the compact SSOP-28.

Output Spot Noise Voltage	e_N	f = 1 kHz, BW = 1 Hz		7		nV√Hz

[1] All static performance tests (except I_{OUT}) are performed in a closed-loop system using an external precision OP177 I-to-V converter amplifier. The AD5544 R_{FB} terminal is tied to the amplifier output. Typical values represent average readings measured at 25 °C.
[2] These parameters are guaranteed by design and not subject to production testing.
[3] All input control signals are specified with $t_R = t_F$ = 2.5 ns (10% to 90% of 3 V) and timed from a voltage level of 1.5 V.
[4] All ac characteristic tests are performed in a closed-loop system using an OP42 I-to-V converter amplifier.

AD5554 ELECTRICAL CHARACTERISTICS

V_{DD} = 5 V ±10%, V_{SS} = 0 V, $I_{OUT}X$ = virtual GND, $A_{GND}X$ = 0 V, $V_{REF}A$, B, C, D = 10 V, T_A = full operating temperature range, unless otherwise noted.

[1] All static performance tests (except I_{OUT}) are performed in a closed-loop system using an external precision OP177 I-to-V converter amplifier. The AD5554 R_{FB} terminal is tied to the amplifier output. Typical values represent average readings measured at 25°C.
[2] These parameters are guaranteed by design and not subject to production testing.
[3] All input control signals are specified with $t_R = t_F$ = 2.5 ns (10% to 90% of 3 V) and timed from a voltage level of 1.5 V.
[4] All ac characteristic tests are performed in a closed-loop system using an OP42 I-to-V converter amplifier.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
V_{DD} to GND	−0.3 V, +8 V
V_{SS} to GND	+0.3 V, −7 V
V_{REF} to GND	−18 V, +18 V
Logic Input and Output to GND	−0.3 V, +8 V
$V(I_{OUT})$ to GND	−0.3 V, V_{DD}+ 0.3 V
$A_{GND}X$ to DGND	−0.3 V, + 0.3 V
Input Current to Any Pin Except Supplies	±50 mA
Package Power Dissipation	$(T_J$ Max − $T_A)/\theta_{JA}$
Thermal Resistance	θ_{JA}
28-Lead Shrink Surface-Mount (RS-28)	100°C/W
Maximum Junction Temperature (T_J Max)	150°C
Operating Temperature Range: Model A	−40°C to +85°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature:	
RS-28 (Vapor Phase, 60 secs)	215°C
RS-28 (Infrared, 15 secs)	220°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

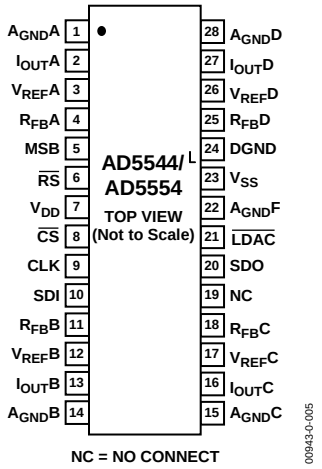

Figure 3. AD5544/AD5554 Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Name	Function
1	$A_{GND}A$	DAC A Analog Ground.
2	$I_{OUT}A$	DAC A Current Output.
3	$V_{REF}A$	DAC A Reference Voltage Input Terminal. Establishes DAC A full-scale output voltage. Pin can be tied to V_{DD} pin.
4	$R_{FB}A$	Establish voltage output for DAC A by connecting to external amplifier output.
5	MSB	MSB Bit. Set pin during a reset pulse ($\overline{RS}$) or at system power ON if tied to ground or V_{DD}.
6	$\overline{RS}$	Reset Pin, Active Low Input. Input registers and DAC registers are set to all zeros or half-scale code (8000_H for AD5544 and 2000_H for AD5554) determined by the voltage on the MSB pin. Register Data = 0000_H when MSB = 0. Register Data = 8000_H for AD5544 and 2000_H.
7	V_{DD}	Positive Power Supply Input. Specified range of operation 5 V ±10%.
8	$\overline{CS}$	Chip Select, Active Low Input. Disables shift register loading when high. Transfers serial register data to the input register when $\overline{CS}$/$\overline{LDAC}$ returns high. Does not effect $\overline{LDAC}$ operation.
9	CLK	Clock Input. Positive edge clocks data into shift register.
10	SDI	Serial Data Input. Input data loads directly into the shift register.
11	$R_{FB}B$	Establish voltage output for DAC B by connecting to external amplifier output.
12	$V_{REF}B$	DAC B Reference Voltage Input Terminal. Establishes DAC B full-scale output voltage. Pin can be tied to V_{DD} pin.
13	$I_{OUT}B$	DAC B Current Output.
14	$A_{GND}B$	DAC B Analog Ground.
15	$A_{GND}C$	DAC C Analog Ground.
16	$I_{OUT}C$	DAC C Current Output.
17	$V_{REF}C$	DAC C Reference Voltage Input Terminal. Establishes DAC C full-scale output voltage. Pin can be tied to V_{DD} pin.
18	$R_{FB}C$	Establish voltage output for DAC C by connecting to external amplifier output.
19	NC	No Connect. Leave pin unconnected.
20	SDO	Serial Data Output. Input data loads directly into the shift register. Data appears at SDO, 19 clock pulses for AD5544 and 17 clock pulses for AD5554 after input at the SDI pin.
21	$\overline{LDAC}$	Load DAC Register Strobe, Level Sensitive Active Low. Transfers all input register data to DAC registers. Asynchronous active low input. See Table 5 and Table 6 for operation.
22	AGNDF	High Current Analog Force Ground.
23	VSS	Negative Bias Power Supply Input. Specified range of operation: −5.5 V to +0.3 V.
24	DGND	Digital Ground Pin.
25	$R_{FB}D$	Establish Voltage Output for DAC D by Connecting to External Amplifier Output.
26	$V_{REF}D$	DAC D Reference Voltage Input Terminal. Establishes DAC D full-scale output voltage. Pin can be tied to V_{DD} pin.
27	$I_{OUT}D$	DAC D Current Output.
28	$A_{GND}D$	DAC D Analog Ground.

CIRCUIT OPERATION

The AD5544 and AD5554 contain four, 16-bit and 14-bit, current-output, digital-to-analog converters, respectively. Each DAC has its own independent multiplying reference input. Both the AD5544 and the AD5554 use a 3-wire, SPI compatible, serial data interface, with a configurable asynchronous $\overline{RS}$ pin for half-scale (MSB = 1) or zero-scale (MSB = 0) preset. In addition, an $\overline{LDAC}$ strobe enables four channel simultaneous updates for hardware synchronized output voltage changes.

D/A CONVERTER

Each part contains four current-steering R-2R ladder DACs. Figure 25 shows a typical equivalent DAC. Each DAC contains a matching feedback resistor for use with an external I-to-V converter amplifier. The $R_{FB}X$ pin connects to the output of the external amplifier. The $I_{OUT}X$ terminal connects to the inverting input of the external amplifier. The $A_{GND}X$ pin should be Kelvin-connected to the load point requiring full 16-bit accuracy. These DACs are designed to operate with both negative or positive reference voltage. The V_{DD} power pin is only used by the logic to drive the DAC switches on and off. Note that a matching switch is used in series with the internal 5 kΩ feedback resistor. If users attempt to measure the value of R_{FB}, power must be applied to V_{DD} in order to achieve continuity. An additional VSS bias pin is used to guard the substrate during high temperature applications, minimizing zero-scale leakage currents that double every 10°C. The DAC output voltage is determined by V_{REF} and the digital data (D) in the following equations:

$$V_{OUT} = -V_{REF} \times \frac{D}{65536} \left(For\ AD5544\right) \quad (1)$$

$$V_{OUT} = -V_{REF} \times \frac{D}{16384} \left(For\ AD5554\right) \quad (2)$$

Note that the output polarity is opposite to the V_{REF} polarity for dc reference voltages.

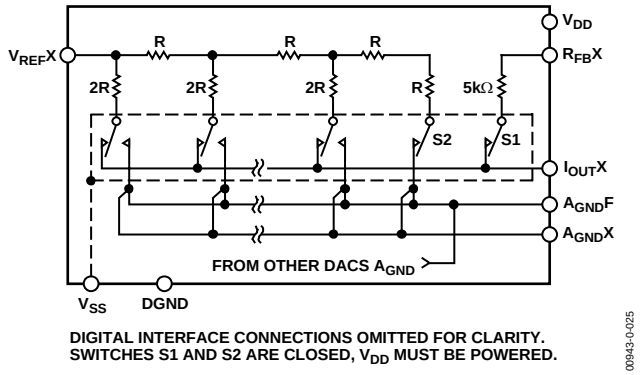

Figure 25. Typical Equivalent DAC Channel

These DACs are also designed to accommodate ac reference input signals. Both the AD5544 and the AD5554 accommodate input reference voltages in the range of −12 V to +12 V. The reference voltage inputs exhibit a constant nominal input resistance of 5 kΩ, ±30%. On the other hand, the DAC outputs IOUTA, B, C, D are code-dependent and produce various output resistances and capacitances. The choice of external amplifier should take into account the variation in impedance generated by the AD5544/AD5554 on the amplifiers' inverting input node. The feedback resistance, in parallel with the DAC ladder resistance, dominates output voltage noise. For multiplying mode applications, an external feedback compensation capacitor (C_{FB}) may be needed to provide a critically damped output response for step changes in reference input voltages. Figure 26 and Figure 27 show the gain vs. frequency performance at various attenuation settings using a 23 pF external feedback capacitor connected across the $I_{OUT}X$ and $R_{FB}X$ terminals for AD5544 and AD5554, respectively. In order to maintain good analog performance, power supply bypassing of 0.01 μF, in parallel with 1 μF, is recommended. Under these conditions, a clean power supply with low ripple voltage capability should be used. Switching power supplies is usually not suitable for this application due to the higher ripple voltage and PSS frequency-dependent characteristics. It is best to derive the AD5544/AD5554's 5 V supply from the system's analog supply voltages. Do not use the digital 5 V supply (see Figure 28).

SERIAL DATA INTERFACE

The AD5544/AD5554 uses a 3-wire ($\overline{CS}$, SDI, CLK) SPI compatible serial data interface. Serial data of AD5544 and AD5554 is clocked into the serial input register in an 18-bit and 16-bit data-word format respectively. MSB bits are loaded first. Table 6 defines the 18 data-word bits for AD5544.

Table 7 defines the 16 data-word bits for AD5554. Data is placed on the SDI pin, and clocked into the register on the positive clock edge of CLK subject to the data setup and data hold time requirements specified in the interface timing specifications. data can only be clocked in while the $\overline{CS}$ chip select pin is active low. For AD5544, only the last 18 bits clocked into the serial register will be interrogated when the $\overline{CS}$ pin returns to the logic high state, extra data bits are ignored. For AD5554, only the last 16 bits clocked into the serial register will be interrogated when the $\overline{CS}$ pin returns to the logic high state. Since most microcontrollers output serial data in 8-bit bytes, three right justified data bytes can be written to the AD5544. Keeping the $\overline{CS}$ line low between the first, second, and third byte transfers will result in a successful serial register update. Similarly, two right justified data bytes can be written to the AD5554. Keeping the $\overline{CS}$ line low between the first and second byte transfer will result in a successful serial register update.

Once the data is properly aligned in the shift register, the positive edge of the $\overline{CS}$ initiates the transfer of new data to the target DAC register, determined by the decoding of address Bits A1 and A0. For AD5544, Table 5, Table 7, Table 9, and Figure 4 define the characteristics of the software serial interface. For AD5554, Table 6, Table 8, Table 9, and Figure 5 define the characteristics of the software serial interface. Figure 29 and Figure 30 show the equivalent logic interface for the key digital control pins for the AD5544. AD5554 has a similar configuration, except it has 14 data bits. Two additional pins, $\overline{RS}$ and MSB, provide hardware control over the preset function and DAC register loading.

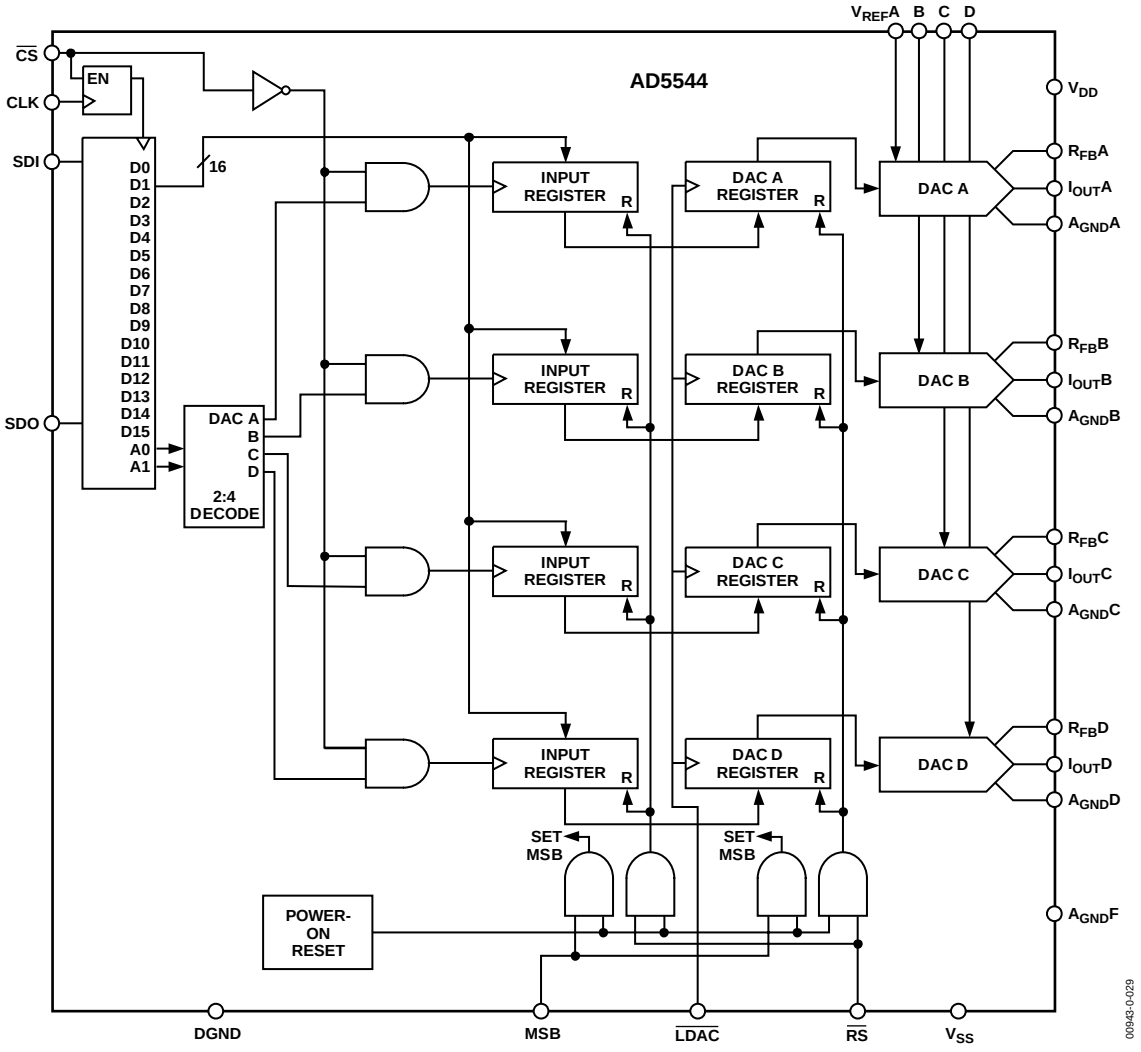

Figure 29. System Level Digital Interfacing

If these functions are not needed, the $\overline{RS}$ pin can be tied to logic high. The asynchronous input $\overline{RS}$ pin forces all input and DAC registers to either the zero-code state (MSB = 0) or the half-scale state (MSB = 1).

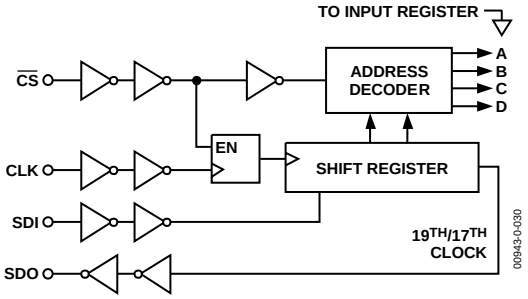

Figure 30. AD5544/AD5554 Equivalent Logic Interface

POWER ON RESET

When the V_{DD} power supply is turned on, an internal reset strobe forces all the input and DAC registers to the zero-code state or half-scale state, depending on the MSB pin voltage. The V_{DD} power supply should have a smooth positive ramp without drooping in order to have consistent results, especially in the region of V_{DD} = 1.5 V to 2.3 V. The V_{SS} supply has no effect on the power-on reset performance. The DAC register data will stay at a zero or half-scale setting until a valid serial register data load takes place.

ESD Protection Circuits

All logic-input pins contain back-biased ESD protection Zeners connected to ground (D_{GND}) and V_{DD}, as shown in Figure 31.

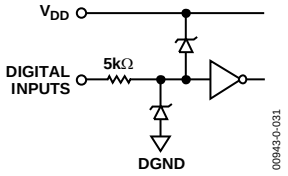

Figure 31. Equivalent ESD Production Circuits

Power Supply Sequence

As standard practice, it is recommended to power V_{DD}, V_{SS}, and ground prior to any reference. The ideal power up sequence is $A_{GND}X$, D_{GND}, V_{DD}, V_{SS}, $V_{REF}X$, and digital inputs. A noncompliance power up sequence may elevate the reference current, but the devices resume normal operation once V_{DD} and V_{SS} are powered-up.

Layout and Power Supply Bypassing

It is good practice to employ a compact, minimum-lead length layout design. The leads to the input should be as direct as possible with a minimum conductor length. Ground paths should have low resistance and low inductance.

Similarly, it is good practice to bypass the power supplies with quality capacitors for optimum stability. Supply leads to the device should be bypassed with 0.01 µF to 0.1 µF disc or chip ceramic capacitors. Low-ESR 1 µF to 10 µF tantalum or electrolytic capacitors should also be applied at V_{DD} to minimize any transient disturbance and filter any low frequency ripple (see Figure 32). Users should not apply switching regulators for V_{DD} due to the power supply rejection ratio degradation over frequency.

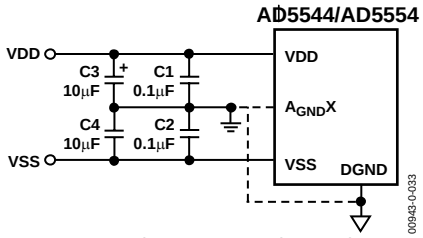

Figure 32. Power Supply Bypassing and Grounding Connection

Grounding

The DGND and AGNDX pins of the AD5544/AD5554 refer as digital and analog ground references. To minimize the digital ground bounce, the DGND terminal should be joined remotely at a single point to the analog ground plane (see Figure 32).

APPLICATIONS

The AD5544/AD5554 are inherently 2-quadrant multiplying D/A converters. That is, they can be easily set up for unipolar output operation. The full-scale output polarity is the inverse of the reference-input voltage.

In some applications it may be necessary to generate the full 4-quadrant multiplying capability or a bipolar output swing. This is easily accomplished using an additional external amplifier (A2) configured as a summing amplifier (see Figure 33). In this circuit the first and second amplifiers (A1 and A2) provide a total gain of 2 which increases the output voltage span to 20 V. Biasing the external amplifier with a 10 V offset from the reference voltage results in a full 4-quadrant multiplying circuit. The transfer equation of this circuit shows that both negative and positive output voltages are created as the input data (D) is incremented from code zero (V_{OUT} = −10 V) to midscale (V_{OUT} = 0 V) to full-scale (V_{OUT} = 10 V).

$$V_{OUT}\left(\frac{D}{32768}-1\right)\times -V_{REF}\ \left(For\ AD5544\right) \quad (3)$$

$$V_{OUT}\left(\frac{D}{8192}-1\right)\times -V_{REF}\ \left(For\ AD5554\right) \quad (4)$$
