## CMOS Parallel Loading

### Dual 12-Bit Multiplying D/A Converters

MX7537/MX7547

#### General Description

The Maxim MX7537/MX7547 contain two 12-bit current-output multiplying digital-to-analog converters (DAC) in a single package. Input level shifters, data registers and control logic make microprocessor interfacing straightforward. Operation is from a single +12V to +15V power supply maintaining TTL, 74HC and 5V CMOS logic compatibility.

The MX7547 accepts  $\overline{CSA}$ ,  $\overline{CSB}$ ,  $\overline{WR}$  control signals and 12 data inputs for DAC selection and full parallel data loading. The MX7537 receives data in 2 bytes, using a right justified 8+4 format.  $A0$ ,  $A1$ ,  $\overline{CS}$ ,  $\overline{WR}$  and  $\overline{UPD}$  signals provide full control for DAC selection and data loading.

Each of the DACs in the MX7537/MX7547 provides 4-quadrant multiplication capabilities and separate reference input and feedback resistor pins. The MX7537 additionally makes available separate AGND pins for applications where each DAC is biased at a different voltage. Since both DACs are on a single monolithic chip, matching and temperature tracking between them is excellent. Gain error is specified at less than  $\pm 1$  LSB, and 12-bit linearity and monotonicity are guaranteed over the full operating temperature ranges.

Maxim's MX7537 and MX7547 are available in narrow 24-lead 0.3" DIP and Wide SO, as well as, 28-pin-lead PLCC packages.

#### Applications

- Automatic Test Equipment
- Audio Gain Control
- Motion Control Systems
- Synchro Applications
- Process Control
- Digitally Controlled Filters

#### Features

- ◆ Two 12-Bit DACs in One Package
- ◆ 0.5% DAC-to-DAC Matching
- ◆ Narrow 0.3" DIP, Wide SO, and PLCC Packages
- ◆ 4-Quadrant Multiplication
- ◆ Low INL and DNL ( $\pm 1/2$  LSB max)
- ◆ Gain Accuracy to  $\pm 1$  LSB max
- ◆ Low Gain Tempco ( $\pm 5$ ppm/ $^{\circ}$ C max)
- ◆ Operates with Single +12V to +15V Supply
- ◆ Fast Microprocessor Interface

#### Ordering Information

PART	TEMP. RANGE	PACKAGE	GAIN ERROR
MX7537JN	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Plastic DIP	$\pm 6$ LSB
MX7537KN	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Plastic DIP	$\pm 3$ LSB
MX7537LN	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Plastic DIP	$\pm 1$ LSB
MX7537JCWG	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Wide SO	$\pm 6$ LSB
MX7537KCWG	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Wide SO	$\pm 3$ LSB
MX7537LCWG	0 $^{\circ}$ C to +70 $^{\circ}$ C	24 Wide SO	$\pm 1$ LSB
MX7537JP	0 $^{\circ}$ C to +70 $^{\circ}$ C	28 PLCC	$\pm 6$ LSB
MX7537KP	0 $^{\circ}$ C to +70 $^{\circ}$ C	28 PLCC	$\pm 3$ LSB
MX7537LP	0 $^{\circ}$ C to +70 $^{\circ}$ C	28 PLCC	$\pm 1$ LSB
MX7537J/D	0 $^{\circ}$ C to +70 $^{\circ}$ C	Dice	$\pm 6$ LSB

# CMOS Parallel Loading Dual 12-Bit Multiplying D/A Converters

## Detailed Description D/A Converter

The basic MX7537/MX7547 circuit includes two identical DACs with laser trimmed, thin-film resistor (R-2R) arrays and NMOS current switches, as shown in Figure 1. Binary weighted currents switch to either  $I_{OUT}$  or GND depending on the status of each input data bit. Although the currents at  $I_{OUT}$  and GND depend on the digital input code, the sum of the two output currents are always equal to the input current at  $V_{REF}$ .

Either current output can be converted to a voltage by adding an external output amplifier (Figures 4, 5). The  $V_{REF}$  input accepts a wide range of signals, including fixed and time varying voltage or current inputs. If a current source is used for the reference input, a low tempco external resistor should be used for  $R_{FB}$  to minimize gain variation with temperature.

Figure 1. Simplified Circuit Diagram for DAC

The internal feedback resistor,  $R_{FB}$ , is compensated with an NMOS switch that matches the NMOS switches used in the R-2R array. This results in excellent supply rejection and gain temperature coefficient.

The  $I_{OUT}$  pin output capacitance,  $C_{OUT}$ , is code dependent and is typically 40pF with all switches connected to GND and 100pF with all switches to  $I_{OUT}$ .

## Digital Circuit

The input buffer inverters of the MX7537/MX7547 act as level shifters converting TTL levels into CMOS logic levels. Logic inputs are TTL, 74HC, and +5V CMOS compatible (0.8V and 2.4V) at  $V_{DD} = +12V$  to  $+15V$ . DAC supply current can be reduced below specified levels by keeping digital input voltages as close to the logic supply and ground as possible (as with CMOS logic levels). All logic inputs are designed to withstand ESD voltages of over 5,000V.

## MX7537 Interface

Figure 2 shows the timing diagram for the MX7537. A1 and A0 select the most-significant (MS) or the least-significant (LS) input registers for DAC A or DAC B (Table 1). When loading the MS register, DB3 is the MSB of the 12-bit data input. Similarly, when the LS register is loaded, DB0 is the LSB. Data is loaded into the DAC when CS and WR both go low. CLR and UPD must be kept high while the data is loaded. When CLR is low, all registers are cleared without regard to the state of other control signals. When UPD and WR are low, the DAC registers are updated simultaneously from the input registers. When UPD, CS and WR are low, the DAC registers are transparent and load the

Figure 2. Timing Diagram for MX7537

# CMOS Parallel Loading Dual 12-Bit Multiplying D/A Converters

data inputs immediately, as selected by the address inputs. Figure 17 shows the control logic equivalent circuit for the MX7537.

### MX7547 Interface

Figure 3 shows the timing diagram for the MX7547. Data is loaded into the DAC A register on the rising edge of WR while CSA is low. Similarly, DAC B register is loaded on the rising edge of WR while CSB is low (Table 2).

Figure 3. Timing Diagram for MX7547

## Circuit Configurations

### Unipolar Operation

Basic applications of the MX7537/MX7547 are shown in Figure 4. These circuits are used for unipolar operation or 2-quadrant multiplication. The code table for this mode is given in Table 3. Note that the polarity of the output is the inverse of the reference voltage,  $V_{IN}$ .

Table 3. Binary Code for Unipolar Circuit

BINARY NUMBER MSB	LSB	$V_{OUTA}$ or $V_{OUTB}$	
1111	1111	1111	$-V_{IN} \left( \frac{4095}{4096} \right)$
1000	0000	0000	$-V_{IN} \left( \frac{2048}{4096} \right) = -1/2 V_{IN}$
0000	0000	0001	$-V_{IN} \left( \frac{1}{4096} \right)$
0000	0000	0000	0V

Figure 4A. MX7537 Unipolar Binary Operation

Figure 4B. MX7547 Unipolar Binary Operation

## CMOS Parallel Loading Dual 12-Bit Multiplying D/A Converters

To adjust the circuits of Figure 4, correct the zero error, if necessary, by loading the appropriate DAC with all 0's code and adjusting the amplifier offset so that  $V_{OUT} = 0V$ . Next, correct the full scale error by loading the DAC with all 1s and adjust resistors R1 (or R3) so that  $V_{OUT} = -V_{IN}(4095/4096)$ .

In many applications, gain adjustment is not necessary if the untrimmed gain accuracy of the DAC is sufficient, or if the gain is trimmed at the voltage reference source. In these cases, resistors R1, R2, R3 and R4 can be omitted. When trimming is used and the DAC is operated over a wide temperature range, then low tempco (<300ppm/°C) resistors should be used for these resistors.

The capacitors C1 and C2 provide phase compensation and reduce overshoot and ringing when fast amplifiers are used at the output of the DAC. Single or dual op amps can be used in this application.

### Bipolar Operation

Figure 5 shows the MX7537/MX7547 operating in the bipolar, or 4-quadrant multiplying mode. These circuits require an additional amplifier and three matched resistors (R3, R4 and R5) for each DAC. The resistors must be of the same material (preferably metal film or wire-wound) for best temperature tracking characteristics (<15ppm/°C), and should match to 0.01% for 12-bit performance. Output code is offset binary and

is listed in Table 4. In multiplying applications, the MSB determines output polarity while the lower eleven bits control amplitude. The MSB can be inverted in software using an exclusive-OR instruction to make the MX7537/MX7547 work with 2's complement coding. Table 5 shows the code relationships to output voltage for 2's complement operation.

**Table 4. Offset Binary Code for Bipolar Circuit**

BINARY NUMBER MSB	LSB	ANALOG OUTPUT
1111	1111 1111	$+V_{IN} \left( \frac{2047}{2048} \right)$
1000	0000 0001	$+V_{IN} \left( \frac{1}{2048} \right)$
1000	0000 0000	0V
0111	1111 1111	$-V_{IN} \left( \frac{1}{2048} \right)$
0000	0000 0000	$-V_{IN} \left( \frac{2048}{2048} \right) = -V_{IN}$

Figure 5A. MX7537 Bipolar Operation (Offset Binary Coding)

# CMOS Parallel Loading Dual 12-Bit Multiplying D/A Converters

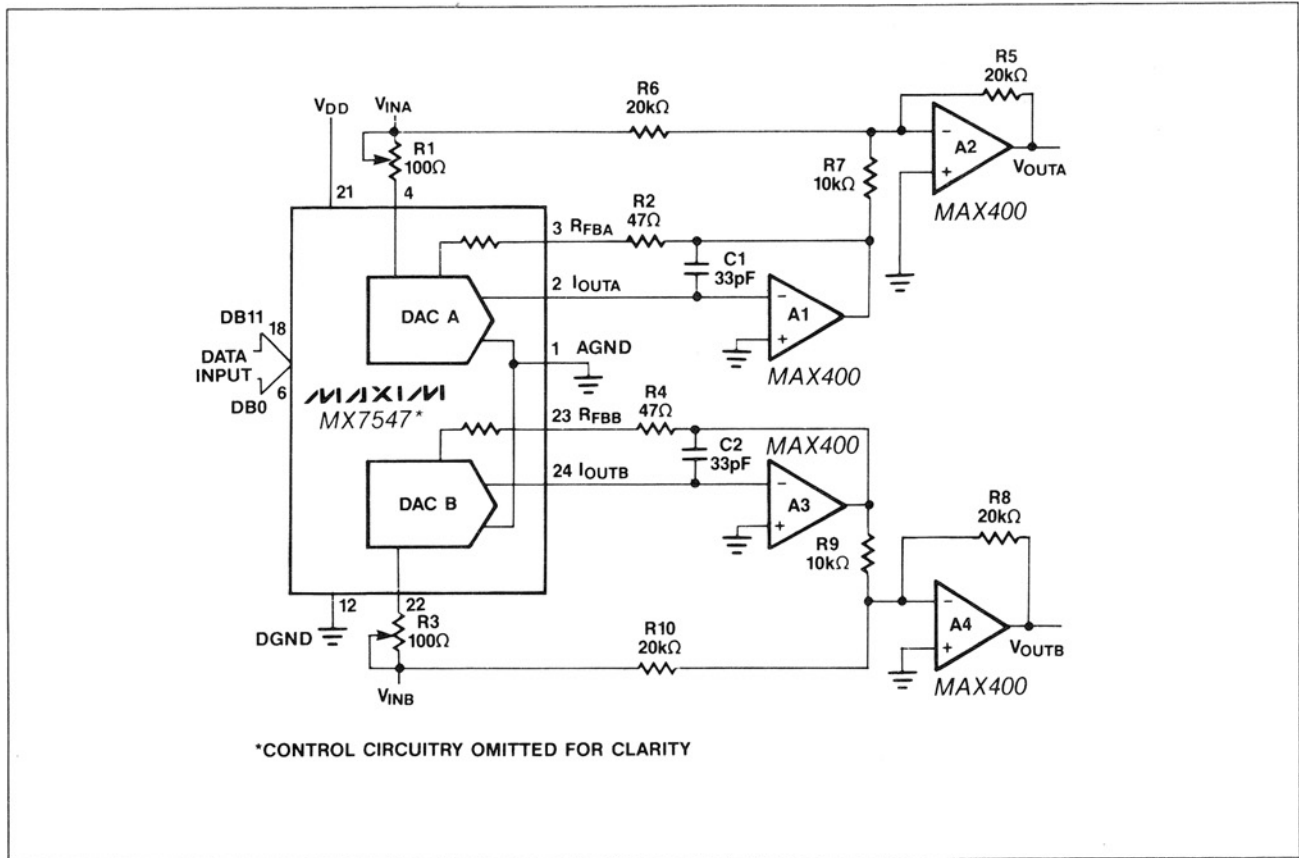

Figure 5B. MX7547 Bipolar Operation (Offset Binary Coding)

Table 5. 2's Complement Code Table

DIGITAL INPUT		ANALOG OUTPUT
MSB	LSB	
0111	1111 1111	$+V_{IN} \left( \frac{2047}{2048} \right)$
0000	0000 0001	$+V_{IN} \left( \frac{1}{2048} \right)$
0000	0000 0000	0
1111	1111 1111	$-V_{IN} \left( \frac{1}{2048} \right)$
1000	0000 0000	$-V_{IN} \left( \frac{2048}{2048} \right)$

To adjust the bipolar circuit, load the DAC with a code of 1000 0000 0000 and trim R1 (or R3) for  $V_{OUT} = 0V$ . With R1 and R2 (or R3 and R4) omitted, an alternative zero trim is to adjust the ratios of R5 and R6 (or R8

and R10) for  $V_{OUT} = 0V$ . Full scale can be trimmed by loading the DAC with all 0s or all 1s and adjusting the amplitude of  $V_{REF}$ , or varying R5 (or R8) until the desired positive or negative output is obtained. In many applications, gain adjustment will not be necessary, especially when using parts with  $\pm 1LSB$  guaranteed maximum gain error. If R1, R2 (or R3, R4) are omitted, then ratio matched 0.01% resistors must be used at R5, R6 and R7 (R8, R9 and R10) for gain error performance to the data sheet specifications. In any case, if the DAC is operated over a wide temperature range, then low tempco ( $<300ppm/^{\circ}C$ ) resistors of the same material will provide best performance.

### Single Supply Applications

The MX7537/MX7547 can be conveniently used in single supply operation with AGND biased at any voltage between DGND and  $V_{DD}$ . Figure 6 shows an MX7547 application which outputs +5V to +10V by biasing AGND at +5V with respect to DGND. The transfer function for each channel is:

$$V_{OUT} = +5V (1 + R_{FB}/R_{EQ})$$

where  $R_{EQ} = \infty$  and  $V_{OUT} = +5V$  with all 0s loaded into the DAC, and  $R_{EQ} = R_{FB}$  and  $V_{OUT} = +10V$  with all 1s in the DAC.

# CMOS Parallel Loading Dual 12-Bit Multiplying D/A Converters

MX7537/MX7547

The MX7537 provides separate AGND pins for DAC A and DAC B which allow the two DACs to be biased at different voltages. In Figure 7, DAC A is connected as a programmable attenuator with AGNDA at DGND. DAC B has a +5V bias at AGNDB, resulting in an output range of +5V to +10V for DAC B.

Figure 8 shows a voltage output DAC connection, where  $I_{OUT}$  is connected to the reference voltage source ( $V_{IN}$ ) and AGND is tied to DGND. This is known as "voltage mode" operation. The DAC output now appears at the  $V_{REF}$  pin which has a constant output impedance equal to the reference input resistance (typically 11k $\Omega$ ).  $R_{FB}$  is not used in this mode.

Two advantages of the voltage mode operation are single supply operation and that a negative reference is not required for a positive output. Limitations are that the reference input ( $I_{OUT}$ ) must be positive and less than 2.5V when  $V_{DD}$  is 15V. If the reference voltage is greater than 2.5V or  $V_{DD}$  is reduced, resistance mismatches in the DAC's internal NMOS switches result in degraded integral (INL) and differential nonlinearity (DNL). For optimum performance,  $V_{IN}$  must stay between 0V and 2.5V, and a buffer amplifier should be used at the DAC outputs and the inputs. Figure 9 shows how the differential linearity is affected by increasing  $V_{IN}$ .

The unipolar and bipolar circuits in Figures 4 and 5 can all be converted to voltage output mode.

## Microprocessor Interface

### MX7537

The MX7537 2-byte interface simplifies the connection to 8-bit microprocessors ( $\mu P$ ). Figures 10 and 11 show interface connections to the MC6809 and MC68008. Figure 12 shows how multiple MX7537s can be used in a  $\mu P$  system by tying all the UPD lines together and controlling these with a single address decoder output. Although this application uses a Z80, any other 8-bit  $\mu P$  can be as easily used.

### MX7547

The 12-bit parallel interface circuit of the MX7547 simplifies the interface to 16-bit  $\mu P$ s. Figures 13 and 14 show 8086 and 68000 interfaces. Possibility of loading invalid data to the DAC is avoided, since the rising edge of the WR signal is used to load the data into the DAC.

## Application Information

### Output Amplifier Offset

For best linearity,  $I_{OUT}$  and AGND should be terminated at exactly 0V. In most applications  $I_{OUT}$  is connected to the summing junction of an inverting op amp. The input offset voltage of the amplifier can

degrade the linearity of the DAC by causing  $I_{OUT}$  to be terminated to a non-zero voltage. The resulting error is:

$$\text{Error Voltage} = V_{OS} (1 + R_{FB}/R_O)$$

where  $V_{OS}$  is the op amp's offset voltage and  $R_O$  is the output resistance of the DAC.  $R_O$  is a function of the digital input code, and varies from approximately 11k $\Omega$  to 33k $\Omega$ . The error voltage range is then typically  $4/3V_{OS}$  to  $2V_{OS}$ , a change of  $2/3V_{OS}$ . An amplifier with 3mV of offset will, therefore, degrade the linearity by 2mV, almost a full LSB with a 10V reference voltage. For best linearity, a low-offset amplifier such as the MAX400 should be used, or the amplifier offset must be trimmed to zero. A good rule of thumb is  $V_{OS}$  should be no more than 1/10LSB.

The output amplifier input bias current ( $I_B$ ) can also limit performance since  $I_B \times R_{FB}$  generates an offset error.  $I_B$  should, therefore, be much less than the DAC output current for 1LSB, typically 250nA with  $V_{REF} = 10V$ . One tenth of this value, 25nA, is recommended. Offset and linearity can also be impaired if the output amplifier noninverting input is grounded through a "bias current compensation resistor." This resistor adds to the offset at this pin and should not be used. Best performance is obtained when the noninverting input is directly connected to ground.

### Dynamic Considerations

In static or DC applications, the AC characteristics of the output amplifier are not critical. In higher speed applications, where either the reference input is an AC signal or the DAC output must quickly settle to a new programmed value, the AC parameters of the output op amp must be considered.

Another error source in dynamic applications is parasitic coupling of signal from the  $V_{REF}$  pin to  $I_{OUT}$ . This normally is a function of board layout and lead-to-lead package capacitance. Noise signals can also be injected into the DAC outputs when the digital inputs are switched. This digital feedthrough is usually dependent on circuit board layout and on-chip capacitive coupling. Layout induced feedthrough can be minimized with guard traces between the digital input,  $V_{REF}$ , and  $I_{OUT}$  pins. Suggested PC board layouts that minimize the parasitic signal feedthrough from  $V_{REFA}$  and  $V_{REFB}$  to the DAC outputs in multiplying applications are shown in Figures 15 and 16.

### Compensation

A compensation capacitor, C1 (C2), may be required when the DAC is used with a high speed output amplifier. The purpose of the capacitor is to cancel the pole formed by the DAC output capacitance,  $C_{OUT}$ , and the internal feedback resistor,  $R_{FB}$ . Its value depends on the type of op amp used but typically ranges from 10pF to 33pF. Too small a value causes output ringing while excess capacitance over-damps the output. The size of C1 (C2) can be minimized and the output voltage settling time improved by keeping the circuit board trace and stray capacitance at  $I_{OUT}$  as low as possible.

### Grounding and Bypassing

Since  $I_{OUT}$  and the noninverting input of the output amplifier are sensitive to offset voltages, nodes that are to be grounded should be connected directly to a "single point" ground through a separate, low resistance (less than  $0.2\Omega$ ) connection. The current at  $I_{OUT}$  and AGND varies with input code, creating a code dependent error if these terminals are connected to ground (or a "virtual ground") through a resistive path.

A  $1\mu F$  bypass capacitor, in parallel with a  $0.01\mu F$  ceramic capacitor, should be connected across  $V_{DD}$  and DGND as close to the device pins as possible.

The MX7537/MX7547 have high impedance digital inputs. To minimize noise pick-up, they should be tied to either  $V_{DD}$  or DGND when not used. It is good practice to connect active inputs to  $V_{DD}$  or DGND through high valued resistors ( $1M\Omega$ ) to prevent static charge accumulation if the pins are left floating, such as when a circuit card is left unconnected.
