## SMBus Dual Monolithic High Side Switch

## features

- Two 0.4 $2 / 300 \mathrm{~mA}$ N-Channel Switches
- Available in MS8 and SO-8 Packages
- SMBus and I ${ }^{2}$ C Compatible
- $0.6 \mathrm{~V} \mathrm{~V}_{\mathrm{IL}}$ and $1.4 \mathrm{~V} \mathrm{~V}_{\mathrm{HH}}$ for DATA and CLK
- Low Standby Current: $14 \mu \mathrm{~A}$
- Separate Drain Connection to SWO
- Three Addresses from One Three-State Address Pin
- Independent Control of Up to Six Switches
- Built-In Power-On Reset Timer
- Built-In Undervoltage Lockout

## APPLICATIONS

- Handheld Computer Power Management
- Computer Peripheral Control
- Laptop Computer Power Plane Switching
- Portable Equipment Power Control
- Industrial Control Systems
- ACPI SMBus Interface

## DESCRIPTIOn

The LTC ${ }^{\circledR} 1710$ SMBus dual switch has two built-in $0.4 \Omega /$ 300 mA switches that are controlled by a 2 -wire SMBus interface. With a low standby current of $14 \mu \mathrm{~A}(3.3 \mathrm{~V})$, the LTC1710 operates over an input voltage range of 2.7 V to 5.5 V while maintaining the SMB 號 specified $0.6 \mathrm{~V} \mathrm{~V}_{\text {IL }}$ and $1.4 \mathrm{~V} \mathrm{~V}_{\mathrm{IH}}$ input thresholds.
Using the 2-wire interface, CLK and DATA, the LTC1710 follows SMBus's Send Byte Protocol to independently control the two $0.4 \Omega$ internal N -channel power switches, which are fully enhanced by onboard charge pumps.
The LTC1710 has one three-state programmable address pin that allows three different addresses for a total of six available switches on the same bus. The LTC1710 also features a separate user-controlled drain supply (SWOD) to Switch 0 so that it can be used to control SMBus peripherials using a different power supply.
$\boldsymbol{\triangle}$, LTC and LT are registered trademarks of Linear Technology Corporation.

The - denotes specifications which apply over the full operating temperature range.
Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.
Note 2: Approximately 3\% hysteresis is provided to ensure stable operation and eliminate false triggering by minor $V_{C C}$ glitches.
Note 3: Measured from $V_{C C}>V_{\text {UVLO }}$ to SMBus ready for DATA input.

Note 4: The oscillator frequency is not tested directly but is inferred from turn-on time.
Note 5: SMBus timing specifications are guaranteed but not tested.
Note 6: ON is enabled upon receiving the Stop condition from the SMBus master.
Note 7: OFF is enabled upon receiving the Stop condition from the SMBus master.

## TYPICAL PGRFORmRACE CHARACTERISTICS

## PIn functions

SWOD (Pin 1): Drain Supply of Switch 0. User-programmable from OV to $\mathrm{V}_{\mathrm{CC}}$.

OUTO (Pin 2): Source Output of Switch 0. Maximum load of 300 mA ; controlled by LSB of command byte.
AD1 (Pin 3): Three-State Programmable Address Pin. Must be connected directly to $\mathrm{V}_{\mathrm{CC}}$, GND or $\mathrm{V}_{\mathrm{CC}} / 2$ (using two resistors $\leq 1 \mathrm{M}$ ). Do not float this pin.
GND (Pin 4): Ground Connection.

CLK (Pin 5): Serial Clock Interface. Must be pulled high to $V_{C C}$ with external resistor. The pull-up current must be limited to $350 \mu \mathrm{~A}$.
DATA (Pin 6): Open-Drain Connected Serial Data Interface. Must be pulled high to $\mathrm{V}_{\mathrm{CC}}$ with external resistor. The pull-up current must be limited to $350 \mu \mathrm{~A}$.
OUT1 (Pin 7): Source Output of Switch 1. Maximum Ioad of 300 mA ; controlled by 2 nd LSB of command byte.
$\mathbf{V}_{\text {cc }}$ (Pin 8): Input Supply Voltage. Operating range from 2.7V to 5.5V.

## BLOCK DIAGRAM

## TIMING DIAGRFI

## OPERATION

## SMBus Operation

SMBus is a serial bus interface that uses only two bus lines, DATA and CLK, to control low power peripheral devices in portable equipment. It consists of masters, also known as hosts, and slave devices. The master of the SMBus is always the one to initiate communications to the slave devices by varying the status of the DATA and CLK lines. The SMBus specification establishes a set of protocols that devices on the bus must follow for communications.

The protocol that the LTC1710 uses is the Send Byte Protocol. In this protocol, the master first sends out a Start signal by switching the DATA line from high to low while CLK is high. (Because there may be more than one master on the same bus, an arbitration process takes place if two masters attempt to take control of the DATA line simultaneously; the first master that outputs a one while the other master is zero loses the arbitration and becomes a slave itself.) Upon detecting this Start signal, all slave devices on the bus wake up and prepare to shift in the next byte of data.

## operation

The master then sends out the first byte. The first seven bits of this byte consist of the address of the device that the master wishes to communicate with. The last bit indicates whether the command will be a read (logic one) or write (logic zero). Because the LTC1710 is a slave device that can only be written to by a master, it will ignore the ensuing commands of the master if it wants to read from the LTC1710, even if the address sent by the master matches that of the LTC1710. After reception of the first byte, the slave device (LTC1710) with the matching address then acknowledges the master by pulling the DATA line low before the next rising clock edge.
By now all other nonmatching slave devices will have gone back to their original standby states to wait for the next Start signal. Meanwhile, upon receiving the acknowledge from the matching slave, the master then sends out the command byte (see Table 1).

Table 1. Switch Control Table

| COMMAND | XXXXXX00 | XXXXXX01 | XXXXXX10 | XXXXXX11 |
| :--- | :---: | :---: | :---: | :---: |
| Switch 0 | SW0 0ff | SW0 On | SW0 0ff | SW0 0n |
| Switch 1 | SW1 0ff | SW1 0ff | SW1 0n | SW1 On |

After receiving the command byte, the slave device (LTC1710) needs to acknowledge the master again by pulling the DATA line low on the following clock cycle. The master then ends this Send Byte Protocol by sending the Stop signal, which is a transition from low to high on the DATA line while the CLK line is high. Valid data is shifted into the output latch on the last acknowledge signal; the output switch will not turn on, however, until the Stop signal is detected. This double buffering feature of the output latch allows the user to "daisy-chain" multiple SMBus devices such that their outputs are synchronously
executed on the Stop signal despite the fact that valid data were loaded into their output latches at different times. An example is shown in Figure 1. If somehow either the Start or the Stop signal is detected in the middle of a byte, the slave device (LTC1710) will regard this as an error and reject all previous data.

## Address

The LTC1710 has an address of 10110XX; the five MSBs are hardwired, but the two LSBs are programmable by the user with the help of a three-state address pin. Refer to Table 2 for the pin configurations and their corresponding addresses.

Table 2. Address Pin Truth Table

| AD1 | ADDRESS |
| :---: | :---: |
| GND | 1011000 |
| $\mathrm{~V}_{\text {CC }} / 2$ | 1011001 |
| $\mathrm{~V}_{\text {CC }}$ | 1011010 |

To conserve standby current, it is preferable to tie the address pins to either $V_{C C}$ or GND. If three LTC1710s are needed, then the address pin can be tied to the third state of $V_{C C} / 2$ by using two equal value resistors ( $\leq 1 \mathrm{M}$ ), see Figure 2.

Figure 1. Daisy-Chain Example
Example of Send Byte Protocol to Slave Address 1011000 Turning SWO and SW1 On

## operation

## Charge Pump

To fully enhance the internal $N$-channel power switches, an internal charge pump is used to boost the gate drive to a maximum of 6 V above $\mathrm{V}_{\mathrm{Cc}}$. The reason for the maximum charge pump output voltage limit is to protect the internal switches from excessive gate overdrive. A feedback network is used to limit the charge pump output once it is 6 V above $\mathrm{V}_{c c}$. To prevent the power switches from turning on too fast, an internal current source is placed between the output of the charge pump and the gate of the power switch to control the ramp rate.

Since the charge pumps are driving just the gates of the internal switches, only a small amount of current is required. Therefore, all the charge pump capacitors are integrated onboard. The drain of switch 1 is internally connected to $\mathrm{V}_{\mathrm{CC}}$, however, the drain of switch 0 is user controlled through Pin 1. In other words, SMBus devices using different power supply voltages can be simultaneously switched by the same LTC1710.

## Power-On Reset and Undervoltage Lockout

The LTC1710 starts up with both gate drives low. An internal power-on reset (POR) signal inhibits operation
until about $300 \mu \mathrm{~s}$ after $\mathrm{V}_{C C}$ crosses the undervoltage lockout threshold (typically 2V). The circuit includes some hysteresis and delay to avoid nuisance resets. Once operation begins, $\mathrm{V}_{\mathrm{CC}}$ must drop below the threshold for at least $100 \mu$ s to trigger another POR sequence.

## Input Threshold

Anticipating the trend of lower and lower supply voltages, the SMB us is specified with a $\mathrm{V}_{\mathrm{IH}}$ of 1.4 V and $\mathrm{V} \mathrm{V}_{\text {IL }}$ of 0.6 V . While some SMBus parts may violate this stringent SMBus specification by specifying a higher $V_{I H}$ value for a corresponding higher input supply voltage, the LTC1710 meets and maintains the constant SMBus input threshold specification throughout the entire supply voltage range of 2.7 V to 5.5 V .

## Thermal Shutdown

In the unlikely event that either power switch overheats, a thermal shutdown circuit, which is placed closely to the two switches, will activate and turn off the gate drives to both switches. The thermal shutdown circuit has a threshold of $120^{\circ} \mathrm{C}$ with a $15^{\circ} \mathrm{C}$ hysteresis.

## TYPICAL APPLICATIONS

The LTC1710, when used with the LT ${ }^{\oplus} 1521-3.3$, can switch a regulated $3.3 \mathrm{~V} / 300 \mathrm{~mA}$ supply to a load (Figure 3 ). Also, with the help of the LT1304-5, the LTC1710 can be

Figure 3. Low Dropout Regulator Switching a 3.3V/300mA Supply
used to make a boost switching regulator with output disconnect and a low standby current of $22 \mu \mathrm{~A}$ (Figure 5).
