## 74HC/HCT4059 Programmable divide-by-n counter

PHILIPS

## FEATURES

- Synchronous programmable divide-by-n counter
- Presettable down counter
- Fully static operation
- Mode select control of initial decade counting function (divide-by-10, 8, 5, 4 and 2)
- Master preset initialization
- Latchable output
- Easily cascadable with other counters
- Four operating modes: timer divider-by-n divide-by-10 000 master preset
- Output capability: standard
- I ICC category: MSI

## GENERAL DESCRIPTION

The 74HC/HCT4059 are high-speed Si-gate CMOS devices and are pin compatible with the " 4059 " of the "4000B" series. They are specified in compliance with JEDEC standard no. 7A.

The $74 \mathrm{HC} / \mathrm{HCT} 4059$ are divide-by-n counters which can be programmed to divide an input frequency by any number ( n ) from 3 to 15999 . There are four operating modes, timer, divide-by-n, divide-by-10 000 and master preset, which are defined by the mode select inputs ( $\mathrm{K}_{\mathrm{a}}$ to $\mathrm{K}_{\mathrm{c}}$ ) and the latch enable input (LE) as shown in the Function table.

The complete counter consists of a first counting stage, an intermediate counting stage and a fifth counting stage. The first counter stage consists of four independent flip-flops. Depending on the divide-by-mode, at least one flip-flop is placed at the input of the intermediate stage (the remaining flip-flops are placed at the fifth stage with a place value of thousands). The intermediate stage consists of three cascaded decade counters, each containing four flip-flops.

All flip-flops can be preset to a desired state by means of the JAM inputs ( $J_{1}$ to $J_{16}$ ), during which the clock input (CP) will cause all stages to count from n to zero. The zero-detect circuit will then cause all stages to return to the JAM count, during which an output pulse is generated. In the timer mode, after an output pulse is generated, the output pulse remains HIGH until the latch input (LE) goes LOW. The counter will advance, even if LE is HIGH and the output is latched in the HIGH state.

In the divide-by-n mode, a clock cycle wide pulse is generated with a frequency rate equal to the input frequency divided by n .

The function of the mode select and JAM inputs are illustrated in the following examples. In the divide-by-2 mode, only one flip-flop is needed in the first counting section. Therefore the last (5th) counting section has three flip-flops that can be preset to a maximum count of seven with a place value of thousands. This counting mode is selected when $\mathrm{K}_{\mathrm{a}}$ to $\mathrm{K}_{\mathrm{c}}$ are set HIGH. In this case input $\mathrm{J}_{1}$ is used to preset the first counting section and $J_{2}$ to $J_{4}$ are used to preset the last (5th) counting section.

If the divide-by-10 mode is desired for the first section, $\mathrm{K}_{\mathrm{a}}$ and $K_{b}$ are set HIGH and $K_{c}$ is set LOW. The JAM inputs $J_{1}$ to $J_{4}$ are used to preset the first counting section (there is no last counting section). The intermediate counting section consists of three cascaded BCD decade (divide-by-10) counters, presettable by means of the JAM inputs $J_{5}$ to $J_{16}$.

The preset of the counter to a desired divide-by-n is achieved as follows:
$\mathrm{n}=\left(\mathrm{MODE}^{(1)}\right)(1000 \mathrm{x}$ decade 5 preset
$+100 \times$ decade 4 preset
$+10 \times$ decade 3 preset
$+1 \times$ decade 2 preset)

+ decade 1 preset
To calculate preset values for any " n " count, divide the " n " count by the selected mode. The resultant is the corresponding preset value of the 5th to the 2nd decade with the remainder being equal to the 1st decade value; preset value $=\mathrm{n} /$ mode .
If $n=8479$, and the selected mode $=5$, the preset value $=8479 / 5=1695$ with a remainder of 4 , thus the JAM inputs must be set as shown in Table 1.

To verify the results, use the given equation:
$n=5(1000 \times 1+100 \times 6+10 \times 9+1 \times 5)+4$
$\mathrm{n}=8479$.
If $\mathrm{n}=12382$ and the selected mode $=8$, the preset value $=12382 / 8=1547$ with a remainder of 6 , thus the JAM inputs must be set as shown in Table 2.

To verify:
$\mathrm{n}=8(1000 \times 1+100 \times 5+10 \times 4+1 \times 7)+6$
$\mathrm{n}=12382$.
(1) $\mathrm{MODE}=$ first counting section divider
(10, 8, 5, 4 or 2).

If $\mathrm{n}=8479$ and the selected mode $=10$, the preset value $=8479 / 10$ with a remainder of 9 , thus the JAM inputs must be set as shown in Table 3.

To verify:
$\mathrm{n}=10(1000 \times 0+100 \times 8+10 \times 4+1 \times 7)+9$
$\mathrm{n}=8479$.
The three decades of the intermediate counting section can be preset to a binary 15 instead of a BCD 9 . In this case the first cycle of a counter consists of 15 count pulses, the next cycles consisting of 10 counting pulses. Thus the place value of the three decades are still 1,10 and 100. For example, in the divide-by-8 mode, the number from which the intermediate counting section begins to count-down can be preset to:

3rd decade: 1500
2nd decade: 150
1st decade: 15
The last counting section can be preset to a maximum of 1 , with a place value of 1000 . The first counting section can be preset to a maximum of 7 . To calculate n :
$\mathrm{n}=8(1000 \times 1+100 \times 15+10 \times 15+1 \times 15)+7$
$\mathrm{n}=21327$.
21327 is the maximum possible count in the divide-by-8 mode. The highest count of the various modes is shown in the Function table, in the column entitled "binary counter range".

The mode select inputs permit, when used with decimal programming, a non-BCD least significant digit. For example, the channel spacing in a radio is 12.5 kHz , it may be convenient to program the counter in decimal steps of 100 kHz subdivided into 8 steps of 12.5 kHz controlled by the least significant digit. Also frequency synthesizer channel separations of $10,12.5,20,25$ and 50 parts can be chosen by the mode select inputs. This is called "Fractional extension". A similar extension called "Half channel offset" can be obtained in modes 2, 4, 6 and 8, if the JAM inputs are switched between zero and 1,2,3 and 4 respectfully. This is illustrated in Fig.5.

This feature is used primarily in cases where radio channels are allocated according to the following formula:

Channel frequency $=$ channel spacing $\times(N+0.5)$
$N$ is an integer.

Control inputs $\mathrm{K}_{\mathrm{b}}$ and $\mathrm{K}_{\mathrm{c}}$ can be used to initiate and lock the counter in the "master preset" mode. In this condition the flip-flops in the counter are preset in accordance with the JAM inputs and the counter remains in that mode as long as $K_{b}$ and $K_{c}$ both remain LOW. The counter begins to count down from the preset state when a counting mode other than the "master preset" mode is selected. Whenever the "master preset" mode is used, control signals $K_{b}=K_{c}=$ LOW must be applied for at least 2 full clock pulses. After the "master preset" mode inputs have been changed to one of the counting modes, the next positive-going clock transition changes an internal flip-flop so that the count-down begins on the second positive-going clock transition. Thus, after a "master preset" mode, there is always one extra count before the output goes HIGH. Figure 6 illustrates the operation of the counter in the divide-by- 8 mode starting from the preset state 3.

If the "master preset" mode is started two clock cycles or less before an output pulse, the output pulse will appear at the correct moment. When the output pulse appears and the "master preset" mode is not selected, the counter is preset according to the states of the JAM inputs.
When $\mathrm{K}_{\mathrm{a}}, \mathrm{K}_{\mathrm{b}}, \mathrm{K}_{\mathrm{c}}$ and LE are LOW, the counter operates in the "preset inhibit" mode, during which the counter divides at a fixed rate of 10000 , independent of the state of the JAM inputs. However, the first cycle length after leaving the "master preset" mode is determined by the JAM inputs.
When $K_{a}, K_{b}$ and $K_{c}$ are LOW and input LE $=\mathrm{HIGH}$, the counter operates in the normal divide-by-10 mode, however, without the latch operation at the output.

This device is particularly advantageous in digital frequency synthesizer circuits (VHF, UHF, FM, AM etc.) for communication systems, where programmable divide-by-"n" counters are an integral part of the synthesizer phase-locked-loop sub-system. The $74 \mathrm{HC} / \mathrm{HCT} 4059$ can also be used to perform the synthesizer "fixed divide-by-n" counting function, as well as general purpose counting for instrumentation functions such as totalizers, production counters and "time out" timers.

Schmitt-trigger action at the clock input makes the circuit highly tolerant to slower clock rise and fall times.

QUICK REFERENCE DATA
GND $=0 \mathrm{~V} ; \mathrm{T}_{\mathrm{amb}}=25^{\circ} \mathrm{C} ; \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

| SYMBOL | PARAMETER | CONDITIONS | TYPICAL |  | UNIT |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HC | HCT |  |
| $\mathrm{t}_{\text {PHL }} / \mathrm{t}_{\text {PLH }}$ | propagation delay CP to Q | $\mathrm{C}_{\mathrm{L}}=15 \mathrm{pF} ; \mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}$ | 18 | 20 | ns |
| $\mathrm{f}_{\text {max }}$ | maximum clock frequency |  | 40 | 40 | MHz |
| $\mathrm{C}_{1}$ | input capacitance |  | 3.5 | 3.5 | pF |
| $\mathrm{C}_{\text {PD }}$ | power dissipation capacitance per package | notes 1 and 2 | 30 | 32 | pF |

## Notes

1. $C_{P D}$ is used to determine the dynamic power dissipation ( $P_{D}$ in $\left.\mu \mathrm{W}\right)$ :

$$
P_{D}=C_{P D} \times V_{C C}^{2} \times f_{i}+\sum\left(C_{L} \times V_{C C}^{2} \times f_{0}\right) \text { where: }
$$

$f_{i}=$ input frequency in MHz
$\mathrm{f}_{\mathrm{o}}=$ output frequency in MHz
$\sum\left(C_{L} \times V_{C C}{ }^{2} \times f_{0}\right)=$ sum of outputs
$\mathrm{C}_{\mathrm{L}}=$ output load capacitance in pF
$\mathrm{V}_{\mathrm{CC}}=$ supply voltage in V
2. For HC the condition is $\mathrm{V}_{\mathrm{I}}=\mathrm{GND}$ to $\mathrm{V}_{\mathrm{CC}}$

For HCT the condition is $\mathrm{V}_{\mathrm{I}}=\mathrm{GND}$ to $\mathrm{V}_{\mathrm{CC}}-1.5 \mathrm{~V}$

## APPLICATIONS

- Frequency synthesizer, ideally suited for use with
PC74HC/HCT4046A,
PC74HC/HCT7046A and PC74HC/HCT9046A (PLLs)
- Fixed or programmable frequency division
- "Time out" timer

Calculating the minimum and maximum divide-by-n values:
Output frequency range $=87.6$ to 103.8 MHz (CCIR band 2)

Channel spacing frequency $\left(f_{c}\right)=300 \mathrm{kHz}$
Division factor prescaler (k) $=10$
Reference frequency $\left(\mathrm{f}_{\mathrm{r}}\right)=\frac{\mathrm{f}_{\mathrm{c}}}{\mathrm{k}}=\frac{300}{10}=30 \mathrm{kHz}$
Maximum divide-by-n value $=\frac{103.8 \mathrm{MHz}}{300 \mathrm{kHz}}=346$
Minimum divide-by-n value $=\frac{87.6 \mathrm{MHz}}{300 \mathrm{kHz}}=292$
Fixed divide-by-n value $=\frac{3 \mathrm{MHz}}{30 \mathrm{kHz}}=100$
Application of the "4059" as divide-by-n counter allows programming of the channel spacing (shown in equations as 300 kHz ). A channel in the CCIR band 2 is selected by the divide-by-n counter as follows:
channel $=\mathrm{n}-290$

Figure 11 shows a BCD switch compatible arrangement suitable for divide-by-5 and divide-by-8 modes, which can be adapted (with minimal changes) to the other divide-by-modes. In order to be able to preset to any number from 3 to 256000 , while preserving the BCD switch compatible character of the JAM inputs, a rather complex cascading scheme is necessary because the "4059" can never be preset to count less than 3. Logic circuitry is required to detect a condition where one of the numbers to be preset in the " 4059 " is $<3$. In order to simplify the detection logic, only that condition is detected where the JAM inputs to terminals 6,7 and 9 would be LOW during one count. If such a condition is detected, and if at least 1 is expected to be jammed into the MSB counter, the detection logic removes one from the number to be jammed into the MSB counter (with a place value of 2000 times the divide-by-mode) and jams the same 2000 into the " 4059 " by forcing pins 6,7 and 9 HIGH.

The general circuit in Fig. 11 can be simplified considerably if the range of the cascaded counters do not start at a very low value.
Figure 12 shows an arrangement in the divide-by- 4 mode, where the counting range extends in a BCD switch compatible manner from 99003 to 114999.

## Programmable divide-by-n counter

The arrangement shown in Fig. 12 is easy to follow; once during every cycle the programmed digits are jammed in (15 616 in this example) and then a round number of 11000 is jammed in, nine times in succession, by forcing the JAM inputs via AND/OR gates.

Numbers larger than the extended counter range can also be produced by cascading the PC74HC/HCT4059 with some other counting devices. Figure 13 shows such an arrangement where only one fixed divide-by number is desired. The dual flip-flop wired to produce a divide-by-3 count can be replaced by other counters such as the "190", "191", "192", "193", "4017", "4510" and "4516".

In Fig. 13 the divide-by-n sub-system is preset once to a number which represents the least significant digits of the divide-by number ( 15690 in the example shown in Fig.13). The sub-system is then preset twice to a round number (8 000 in the example shown in Fig.13) and multiplied by the number of the divide-by mode ( 2 in the example shown in Fig.13).

To verify:
$15690+2 \times 8000 \times 2=47690$.
It is important that the second counting device has an output that is HIGH or LOW during only one of its counting states.

Each AND gate is $1 / 4$ of PC74HC/HCT08.
Each OR gate is $1 / 3$ of PC74HC/HCT4075.
Each NOR gate is $1 / 2$ of $\mathrm{PC} 74 \mathrm{HC} / \mathrm{HCT} 4002$.
Each inverter is $1 / 6$ of $\mathrm{PC} 74 \mathrm{HC} / \mathrm{HCT} 04$.

Fig. 11 BCD switch compatible divide-by-n system suitable for divide-by- 5 and divide-by- 8 mode. Divides by any number from 3 to 256000.

Fig. 12 Dividing-by any number from 99003 to 114999 (in this example $\mathrm{n}=114616$ ).

Fig. 13 Division by 47690 in divide-by- 2 mode.
(1) $\quad \mathrm{RC} \geq \frac{1}{0.2 \times \mathrm{f}_{\mathrm{CP}}(\mathrm{Hz})}$
(2) It is assumed that the $f_{C P}$ starts directly after the power-on. Any additional delay in starting $\mathrm{f}_{\mathrm{CP}}$ must be added to the RC time.

## SOLDERING

## Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "Data Handbook IC26; Integrated Circuit Packages" (order code 9398652 90011).

## DIP

## SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is $260^{\circ} \mathrm{C}$; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $\mathrm{T}_{\text {stg max }}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

## Repairing soldered joints

Apply a low voltage soldering iron (less than 24 V ) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than $300^{\circ} \mathrm{C}$ it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and $400^{\circ} \mathrm{C}$, contact may be up to 5 seconds.

## SO

## Reflow soldering

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to $250^{\circ} \mathrm{C}$.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at $45^{\circ} \mathrm{C}$.

## Wave soldering

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is $260^{\circ} \mathrm{C}$, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than $150^{\circ} \mathrm{C}$ within 6 seconds. Typical dwell time is 4 seconds at $250^{\circ} \mathrm{C}$.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

## Repairing soldered joints

Fix the component by first soldering two diagonallyopposite end leads. Use only a low voltage soldering iron (less than 24 V ) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to $300^{\circ} \mathrm{C}$. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and $320^{\circ} \mathrm{C}$.

## DEFINITIONS

| Data sheet status |  |
| :--- | :--- |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values |  |
| Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or <br> more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation <br> of the device at these or at any other conditions above those given in the Characteristics sections of the specification <br> is not implied. Exposure to limiting values for extended periods may affect device reliability. |  |
| Application information | Where application information is given, it is advisory and does not form part of the specification. |

## LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
