technology available in DIP and SOP packages.

The HCF4052B analog multiplexer/demultiplexer is a digitally controlled analog switch having low ON impedance and very low OFF leakage current. This multiplexer circuit dissipate extremely low quiescent power over the full  $V_{DD}$  -  $V_{SS}$  and  $V_{DD}$  -  $V_{EE}$  supply voltage range, independent of the logic state of the control signals.

When a logic "1" is present at the inhibit input terminal all channel are off. This device is a differential 4-channel multiplexer having two binary control inputs, A and B and an inhibit input. The two binary input signals selects 1 of 4 pairs of channels to be turned on and connect the analog inputs to the outputs.

#### **TYPICAL BIAS VOLTAGES**

The ADDRESS (digtal-control inputs) and INHIBIT logic levels are : "0"=V<sub>SS</sub> and "1"=V<sub>DD</sub>. The analog signal (through the TG) may swing from V<sub>EE</sub> to V<sub>DD</sub>

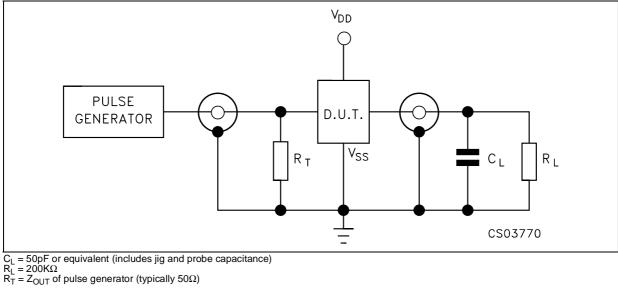

#### TYPICAL APPLICATIONS (TYPICAL TIME-DIVISION APPLICATION)

#### SPECIAL CONSIDERATIONS

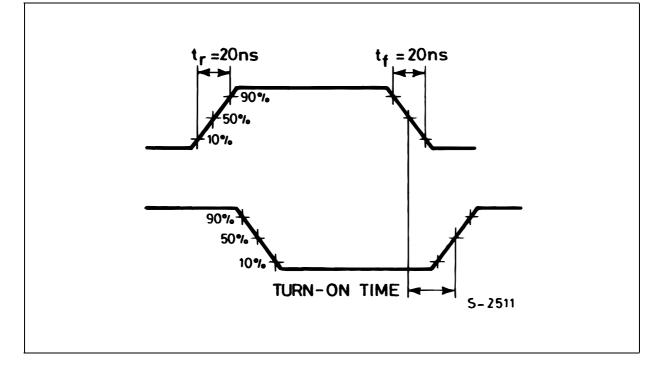

Control of analog signals up to 20V peak to peak can be achieved by digital signal amplitudes of 4.5 to 20V (if  $V_{DD} - V_{SS} = 3V$ , a  $V_{DD} - V_{EE}$  of up to 13V can be controlled; for  $V_{DD} - V_{EE}$  level differences above 13V, a  $V_{DD} - V_{SS}$  of at least 4.5V is required. For example, if  $V_{DD} = +5$ ,  $V_{SS} = 0$ , and  $V_{EE} = -13.5$ , analog signals from -13.5V to 4.5V can be controlled by digital inputs of 0 to 4.5V. In certain applications, the external load resistor current may include both V<sub>DD</sub> and signal-line components. To avoid drawing V<sub>DD</sub> current when switch current flows into the transmission gate inputs, the voltage drop across the bidirectional switch must not exceed 0,8V (calculated from R<sub>ON</sub> values shown in DC SPECIFICATIONS). No V<sub>DD</sub> current will flow through R<sub>L</sub> if the switch current flows into leads 3 and 13.
