

## High Voltage Synchronous Rectified Buck MOSFET Driver

The ISL6208 is a high frequency, dual MOSFET driver, optimized to drive two N-Channel power MOSFETs in a synchronous-rectified buck converter topology. It is especially suited for mobile computing applications that require high efficiency and excellent thermal performance. This driver, combined with an Intersil multiphase Buck PWM controller, forms a complete single-stage core-voltage regulator solution for advanced mobile microprocessors.

The ISL6208 features 4A typical sinking current for the lower gate driver. This current is capable of holding the lower MOSFET gate off during the rising edge of the Phase node. This prevents shoot-through power loss caused by the high dv/dt of phase voltages. The operating voltage matches the 30V breakdown voltage of the MOSFETs commonly used in mobile computer power supplies.

The ISL6208 also features a three-state PWM input that, working together with Intersil's multiphase PWM controllers, will prevent negative voltage output during CPU shutdown. This feature eliminates a protective Schottky diode usually seen in a microprocessor power systems.

MOSFET gates can be efficiently switched up to 2MHz using the ISL6208. Each driver is capable of driving a 3000pF load with propagation delays of 8ns and transition times under 10ns. Bootstrapping is implemented with an internal Schottky diode. This reduces system cost and complexity, while allowing the use of higher performance MOSFETs. Adaptive shoot-through protection is integrated to prevent both MOSFETs from conducting simultaneously.

A diode emulation feature is integrated in the ISL6208 to enhance converter efficiency at light load conditions. This feature also allows for monotonic start-up into pre-biased outputs. When diode emulation is enabled, the driver will allow discontinuous conduction mode by detecting when the inductor current reaches zero and subsequently turning off the low side MOSFET gate.

## Features

- Dual MOSFET Drives for Synchronous Rectified Bridge
- Adaptive Shoot-Through Protection
- 0.5Ω On-Resistance and 4A Sink Current Capability
- Supports High Switching Frequency up to 2MHz
  - Fast output rise and fall time
  - Low propagation delay
- Three-State PWM Input for Power Stage Shutdown
- Internal Bootstrap Schottky Diode
- Low Bias Supply Current (5V, 80μA)
- Diode Emulation for Enhanced Light Load Efficiency and Pre-Biased Start-Up Applications
- VCC POR (Power-On-Reset) Feature Integrated
- Low Three-State Shutdown Holdoff Time (Typical 160ns)
- Pin-to-Pin Compatible with ISL6207
- QFN Package:
  - Compliant to JEDEC PUB95 MO-220 QFN - Quad Flat No Leads - Package outline
  - Near Chip Scale Package footprint, which improves PCB efficiency and has a thinner profile
- Pb-Free available (RoHS compliant)

## Applications

- Core Voltage Supplies for Intel® and AMD® Mobile Microprocessors
- High Frequency Low Profile DC/DC Converters
- High Current Low Output Voltage DC/DC Converters
- High Input Voltage DC/DC Converters

**Absolute Maximum Ratings**

Supply Voltage (VCC)	-0.3V to 7V
Input Voltage (V <sub>FCCM</sub> , V <sub>PWM</sub> )	-0.3V to VCC + 0.3V
BOOT Voltage (V <sub>BOOT-GND</sub> )	-0.3V to 33V
BOOT To PHASE Voltage (V <sub>BOOT-PHASE</sub> )	-0.3V to 7V (DC) -0.3V to 9V (<10ns)
PHASE Voltage (Note 1)	GND - 0.3V to 30V GND - 8V (<20ns Pulse Width, 10μJ)
UGATE Voltage	V <sub>PHASE</sub> - 0.3V (DC) to V <sub>BOOT</sub> V <sub>PHASE</sub> - 5V (<20ns Pulse Width, 10μJ) to V <sub>BOOT</sub>
LGATE Voltage	GND - 0.3V (DC) to VCC + 0.3V GND - 2.5V (<20ns Pulse Width, 5μJ) to VCC + 0.3V
Ambient Temperature Range	-40°C to +125°C

**Thermal Information**

Thermal Resistance (Typical)	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)
SOIC Package (Note 2)	110	N/A
QFN Package (Notes 3, 4)	80	15
Maximum Storage Temperature Range	-65°C to +150°C	
Pb-Free Reflow Profile	see link below <a href="http://www.intersil.com/pbfree/Pb-FreeReflow.asp">http://www.intersil.com/pbfree/Pb-FreeReflow.asp</a>	

**Recommended Operating Conditions**

Ambient Temperature Range	-10°C to +100°C
Maximum Operating Junction Temperature	+125°C
Supply Voltage, VCC	5V ±10%

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

**NOTES:**

- The Phase Voltage is capable of withstanding -7V when the BOOT pin is at GND.
- $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air. See Tech Brief TB379 for details.
- $\theta_{JA}$  is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
- For  $\theta_{JC}$ , the "case temp" location is the center of the exposed metal pad on the package underside.

**Electrical Specifications** Recommended Operating Conditions, Unless Otherwise Noted. Parameters with MIN and/or MAX limits are 100% tested at +25°C, unless otherwise specified. Temperature limits established by characterization and are not production tested.

Typical Application with 2-Phase Converter

## Timing Diagram

### Functional Pin Description

#### UGATE (Pin 1 for SOIC-8, Pin 8 for QFN)

The UGATE pin is the upper gate drive output. Connect to the gate of high-side power N-Channel MOSFET.

#### BOOT (Pin 2 for SOIC-8, Pin 1 for QFN)

BOOT is the floating bootstrap supply pin for the upper gate drive. Connect the bootstrap capacitor between this pin and the PHASE pin. The bootstrap capacitor provides the charge to turn on the upper MOSFET. See "Internal Bootstrap Diode" on page 8 for guidance in choosing the appropriate capacitor value.

#### PWM (Pin 3 for SOIC-8, Pin 2 for QFN)

The PWM signal is the control input for the driver. The PWM signal can enter three distinct states during operation. See "Three-State PWM Input" on page 8 for further details. Connect this pin to the PWM output of the controller.

#### GND (Pin 4 for SOIC-8, Pin 3 for QFN)

GND is the ground pin for the IC.

#### LGATE (Pin 5 for SOIC-8, Pin 4 for QFN)

LGATE is the lower gate drive output. Connect to gate of the low-side power N-Channel MOSFET.

#### VCC (Pin 6 for SOIC-8, Pin 5 for QFN)

Connect the VCC pin to a +5V bias supply. Place a high quality bypass capacitor from this pin to GND.

#### FCCM (Pin 7 for SOIC-8, Pin 6 for QFN)

The FCCM pin enables or disables Diode Emulation. When FCCM is LOW, diode emulation is allowed. Otherwise, continuous conduction mode is forced. See "Diode Emulation" on page 8 for more detail.

#### PHASE (Pin 8 for SOIC-8, Pin 7 for QFN)

Connect the PHASE pin to the source of the upper MOSFET and the drain of the lower MOSFET. This pin provides a return path for the upper gate driver.

### Description

#### Theory of Operation

Designed for speed, the ISL6208 dual MOSFET driver controls both high-side and low-side N-Channel FETs from one externally provided PWM signal.

A rising edge on PWM initiates the turn-off of the lower MOSFET (see "Timing Diagram" on page 6). After a short propagation delay [ $t_{PDLL}$ ], the lower gate begins to fall. Typical fall times [ $t_{FL}$ ] are provided in the Electrical Specifications section. Adaptive shoot-through circuitry monitors the LGATE voltage. When LGATE has fallen below 1V, UGATE is allowed to turn ON. This prevents both the lower and upper MOSFETs from conducting simultaneously, or shoot-through.

A falling transition on PWM indicates the turn-off of the upper MOSFET and the turn-on of the lower MOSFET. A short propagation delay [ $t_{PDLU}$ ] is encountered before the upper gate begins to fall [ $t_{FU}$ ]. The upper MOSFET gate-to-source voltage is monitored, and the lower gate is allowed to rise after the upper MOSFET gate-to-source voltage drops below 1V. The lower gate then rises [ $t_{RL}$ ], turning on the lower MOSFET.

This driver is optimized for converters with large step-down compared to the upper MOSFET because the lower MOSFET conducts for a much longer time in a switching period. The lower gate driver is therefore sized much larger to meet this application requirement.

The 0.5Ω ON-resistance and 4A sink current capability enable the lower gate driver to absorb the current injected to the lower gate through the drain-to-gate capacitor of the lower MOSFET and prevent a shoot-through caused by the high dv/dt of the phase node.

FIGURE 6. PRE-BIASED START-UP IN CCM MODE

FIGURE 7. PRE-BIASED START-UP IN DCM MODE

### Diode Emulation

Diode emulation allows for higher converter efficiency under light load situations. With diode emulation active, the ISL6208 will detect the zero current crossing of the output inductor and turn off LGATE. This ensures that discontinuous conduction mode (DCM) is achieved. Diode emulation is asynchronous to the PWM signal. Therefore, the ISL6208 will respond to the FCCM input immediately after it changes state. Refer to “Typical Performance Waveforms” on page 7. NOTE: Intersil does not recommend Diode Emulation use with  $r_{DS(ON)}$  current sensing topologies. The turn-OFF of the low side MOSFET can cause gross current measurement inaccuracies.

### Three-State PWM Input

A unique feature of the ISL6208 and other Intersil drivers is the addition of a shutdown window to the PWM input. If the PWM signal enters and remains within the shutdown window for a set holdoff time, the output drivers are disabled and both MOSFET gates are pulled and held low. The shutdown state is removed when the PWM signal moves outside the shutdown window. Otherwise, the PWM rising and falling thresholds outlined in the Electrical Specifications Table on page 3 determine when the lower and upper gates are enabled.

### Adaptive Shoot-Through Protection

Both drivers incorporate adaptive shoot-through protection to prevent upper and lower MOSFETs from conducting simultaneously and shorting the input supply. This is accomplished by ensuring the falling gate has turned off one MOSFET before the other is allowed to turn on.

During turn-off of the lower MOSFET, the LGATE voltage is monitored until it reaches a 1V threshold, at which time the UGATE is released to rise. Adaptive shoot-through circuitry monitors the upper MOSFET gate-to-source voltage during UGATE turn-off. Once the upper MOSFET gate-to-source voltage has dropped below a threshold of 1V, the LGATE is allowed to rise.

### Internal Bootstrap Diode

This driver features an internal bootstrap Schottky diode. Simply adding an external capacitor across the BOOT and PHASE pins completes the bootstrap circuit. The bootstrap capacitor must have a maximum voltage rating above the maximum battery voltage plus 5V. The bootstrap capacitor can be chosen from Equation 1:

$$C_{BOOT} \geq \frac{Q_{GATE}}{\Delta V_{BOOT}} \quad (\text{EQ. 1})$$

where  $Q_{GATE}$  is the amount of gate charge required to fully charge the gate of the upper MOSFET. The  $\Delta V_{BOOT}$  term is defined as the allowable droop in the rail of the upper drive.

As an example, suppose an upper MOSFET has a gate charge,  $Q_{GATE}$ , of 25nC at 5V and also assume the droop in the drive voltage over a PWM cycle is 200mV. One will find that a bootstrap capacitance of at least 0.125 $\mu$ F is required. The next larger standard value capacitance is 0.15 $\mu$ F. A good quality ceramic capacitor is recommended.

FIGURE 8. BOOTSTRAP CAPACITANCE vs. BOOT RIPPLE VOLTAGE

### Power Dissipation

Package power dissipation is mainly a function of the switching frequency and total gate charge of the selected MOSFETs. Calculating the power dissipation in the driver for a desired application is critical to ensuring safe operation. Exceeding the maximum allowable power dissipation level will push the IC beyond the maximum recommended operating junction temperature of +125°C. The maximum allowable IC power dissipation for the SO-8 package is approximately 800mW. When designing the driver into an application, it is recommended that the following calculation be performed to ensure safe operation at the desired frequency for the selected MOSFETs. The power dissipated by the driver is approximated as shown in Equation 2:

$$P = f_{sw}(1.5V_U Q_U + V_L Q_L) + I_{VCC} V_{CC} \quad (\text{EQ. 2})$$

FIGURE 9. POWER DISSIPATION vs FREQUENCY

where  $f_{SW}$  is the switching frequency of the PWM signal.  $V_U$  and  $V_L$  represent the upper and lower gate rail voltage.  $Q_U$  and  $Q_L$  is the upper and lower gate charge determined by MOSFET selection and any external capacitance added to the gate pins. The  $I_{VCC} V_{CC}$  product is the quiescent power of the driver and is typically negligible.

## Layout Considerations

### Reducing Phase Ring

The parasitic inductances of the PCB and power devices (both upper and lower FETs) could cause increased PHASE ringing, which may lead to voltages that exceed the absolute maximum rating of the devices. When PHASE rings below ground, the negative voltage could add charge to the bootstrap capacitor through the internal bootstrap diode. Under worst-case conditions, the added charge could overstress the BOOT and/or PHASE pins. To prevent this

from happening, the user should perform a careful layout inspection to reduce trace inductances, and select low lead inductance MOSFETs and drivers. D<sup>2</sup>PAK and DPAK packaged MOSFETs have high parasitic lead inductances, as opposed to SOIC-8. If higher inductance MOSFETs must be used, a Schottky diode is recommended across the lower MOSFET to clamp negative PHASE ring.

A good layout would help reduce the ringing on the phase and gate nodes significantly:

- Avoid using vias for decoupling components where possible, especially in the BOOT-to-PHASE path. Little or no use of vias for VCC and GND is also recommended. Decoupling loops should be short.
- All power traces (UGATE, PHASE, LGATE, GND, VCC) should be short and wide, and avoid using vias. If vias must be used, two or more vias per layer transition is recommended.
- Keep the SOURCE of the upper FET as close as thermally possible to the DRAIN of the lower FET.
- Keep the connection in between the SOURCE of lower FET and power ground wide and short.
- Input capacitors should be placed as close to the DRAIN of the upper FET and the SOURCE of the lower FET as thermally possible.

Note: Refer to Intersil Tech Brief TB447 for more information.

### Thermal Management

For maximum thermal performance in high current, high switching frequency applications, connecting the thermal pad of the QFN part to the power ground with multiple vias, or placing a low noise copper plane underneath the SOIC part is recommended. This heat spreading allows the part to achieve its full thermal potential.
