# 4-Mb (128K x 36) Pipelined Sync SRAM 

## Features

- Fully registered inputs and outputs for pipelined operation
- 128 K by 36 common I/O architecture
- 3.3 V core power supply
- 2.5V/3.3V I/O operation
- Fast clock-to-output times
- 2.6 ns (for $\mathbf{2 5 0 - M H z}$ device)
- 2.6 ns (for 225-MHz device)
- 2.8 ns (for 200-MHz device)
- 3.5 ns (for $166-\mathrm{MHz}$ device)
- 4.0 ns (for 133-MHz device)
- 4.5 ns (for $100-\mathrm{MHz}$ device)
- User-selectable burst counter supporting Intel ${ }^{\circledR}$ Pentium ${ }^{\circledR}$ interleaved or linear burst sequences
- Separate processor and controller address strobes
- Synchronous self-timed writes
- Asynchronous output enable
- JEDEC-standard 100-pin TQFP, 119-pin BGA and 165-pin fBGA packages
- "ZZ" Sleep Mode option and Stop Clock option
- Available in Industrial and Commercial temperature ranges

## Functional Description ${ }^{[1]}$

The CY7C1347F is a $3.3 \mathrm{~V}, 128 \mathrm{~K}$ by 36 synchronous-pipelined SRAM designed to support zero-wait-state secondary cache with minimal glue logic.
CY7C1347F I/O pins can operate at either the 2.5 V or the 3.3 V level, the I/O pins are 3.3 V tolerant when $\mathrm{V}_{\mathrm{DDQ}}=2.5 \mathrm{~V}$.
All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise is $2.6 \mathrm{~ns}(250-\mathrm{MHz}$ device)

CY7C1347F supports either the interleaved burst sequence used by the Intel Pentium processor or a linear burst sequence used by processors such as the PowerPC ${ }^{\circledR}$. The burst sequence is selected through the MODE pin. Accesses can be initiated by asserting either the Address Strobe from Processor (ADSP) or the Address Strobe from Controller (ADSC) at clock rise. Address advancement through the burst sequence is controlled by the ADV input. A 2-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.

Byte write operations are qualified with the four Byte Write Select ( $\overline{\mathrm{BW}}_{[\mathrm{A}: \mathrm{D}]}$ ) inputs. A Global Write Enable ( $\overline{\mathrm{GW}}$ ) overrides all byte write inputs and writes data to all four bytes. All writes are conducted with on-chip synchronous self-timed write circuitry.
Three synchronous Chip Selects ( $\left.\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}\right)$ and an asynchronous Output Enable ( $\overline{\mathrm{OE} \text { ) provide for easy bank }}$ selection and output three-state control. In order to provide proper data during depth expansion, $\overline{\mathrm{OE}}$ is masked during the first clock of a read cycle when emerging from a deselected state.

## Pin Definitions

| Name (BGA,FBGA) | Name (100TQFP) | I/O | Description |
| :---: | :---: | :---: | :---: |
| $\mathrm{A}_{0}, \mathrm{~A}_{1}, \mathrm{~A}$ | $\mathrm{A}_{\text {[16:0] }}$ | InputSynchronous | Address Inputs used to select one of the 128 K address locations. Sampled at the rising edge of the CLK if $\overline{\mathrm{ADSP}}$ or $\overline{\mathrm{ADSC}}$ is active LOW, and $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}$, and $\overline{\mathrm{CE}}_{3}$ are sampled active. $\mathrm{A}_{[1: 0]}$ feeds the 2-bit counter. |
| $\begin{aligned} & \overline{\mathrm{BW}}_{\mathrm{A}}, \overline{\mathrm{BW}}_{\mathrm{B}}, \overline{\mathrm{BW}}_{\mathrm{B}} \end{aligned}$ | $\overline{\mathrm{BW}}_{[\mathrm{A}: \mathrm{D}]}$ | InputSynchronous | Byte Write Select Inputs, active LOW. Qualified with BWE to conduct byte writes to the SRAM. Sampled on the rising edge of CLK. |
| $\overline{\mathrm{GW}}$ | $\overline{\mathrm{GW}}$ | InputSynchronous | Global Write Enable Input, active LOW. When asserted LOW on the rising edge of CLK, a global write is conducted (ALL bytes are written, regardless of the values on $\overline{\mathrm{BW}}_{[\mathrm{A}: \mathrm{D}]}$ and $\overline{\mathrm{BWE})}$. |
| $\overline{\text { BWE }}$ | $\overline{\text { BWE }}$ | Input- <br> Synchronous | Byte Write Enable Input, active LOW. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write. |
| CLK | CLK | Input-Clock | Clock Input. Used to capture all synchronous inputs to the device. Also used to increment the burst counter when ADV is asserted LOW, during a burst operation. |
| $\overline{\mathrm{CE}}_{1}$ | $\overline{\mathrm{CE}}_{1}$ | InputSynchronous | Chip Enable 1 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\mathrm{CE}_{2}$ and $\overline{\mathrm{CE}}_{3}$ to select/deselect the device. $\overline{\mathrm{ADSP}}$ is ignored if $\overline{\mathrm{CE}}_{1}$ is HIGH. |
| $\mathrm{CE}_{2}$ | $\mathrm{CE}_{2}$ | InputSynchronous | Chip Enable 2 Input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with $\overline{\mathrm{CE}}_{1}$ and $\overline{\mathrm{CE}}_{3}$ to select/deselect the device. |
| $\overline{\mathrm{CE}}_{3}$ | $\overline{\mathrm{CE}}_{3}$ | InputSynchronous | Chip Enable 3 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\mathrm{CE}_{1}$ and $\mathrm{CE}_{2}$ to select/deselect the device. |
| $\overline{\mathrm{OE}}$ | $\overline{\mathrm{OE}}$ | InputAsynchronous | Output Enable, asynchronous input, active LOW. Controls the direction of the I/O pins. When LOW, the I/O pins behave as outputs. When deasserted HIGH, I/O pins are three-stated, and act as input data pins. OE is masked during the first clock of a read cycle when emerging from a deselected state. |
| $\overline{\text { ADV }}$ | $\overline{\text { ADV }}$ | InputSynchronous | Advance Input signal, sampled on the rising edge of CLK. When asserted, it automatically increments the address in a burst cycle. |
| $\overline{\text { ADSP }}$ | $\overline{\text { ADSP }}$ | InputSynchronous | Address Strobe from Processor, sampled on the rising edge of CLK. When asserted LOW, addresses presented to the device are captured in the address registers. $\mathrm{A}_{[1: 0]}$ are also loaded into the burst counter. When ADSP and ADSC are both asserted, only $\overline{\text { ADSP }}$ is recognized. ASDP is ignored when $\overline{\mathrm{CE}}_{1}$ is deasserted HIGH. |
| $\overline{\text { ADSC }}$ | $\overline{\text { ADSC }}$ | InputSynchronous | Address Strobe from Controller, sampled on the rising edge of CLK. When asserted LOW, addresses presented to the device are captured in the address registers. $\mathrm{A}_{[1: 0]}$ are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized. |
| ZZ | ZZ | InputAsynchronous | ZZ "sleep" Input. This active HIGH input places the device in a non-time-critical "sleep" condition with data integrity preserved. For normal operation, this pin has to be LOW or left floating. ZZ pin has an internal pull-down. |
| $\begin{aligned} & \mathrm{DQ}_{\mathrm{A}}, \mathrm{DQ}_{\mathrm{B}} \\ & \mathrm{DQ}_{\mathrm{C}}, \mathrm{DQ}_{\mathrm{D}} \\ & \mathrm{DQP}_{\mathrm{A},}, \mathrm{DQP}_{\mathrm{B}}, \\ & \mathrm{DQP}_{\mathrm{C}}, \mathrm{DQP}_{\mathrm{D}} \end{aligned}$ | $\begin{array}{\|l\|} \hline \text { DQs } \\ \text { DQPs } \end{array}$ | I/O- <br> Synchronous | Bidirectional Data I/O lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by the addresses presented during the previous clock rise of the read cycle. The direction of the pins is controlled by OE. When $\overline{O E}$ is asserted LOW, the pins behave as outputs. When HIGH, DQs and DQPs are placed in a three-state condition. |
| $\mathrm{V}_{\mathrm{DD}}$ | $\mathrm{V}_{\mathrm{DD}}$ | Power Supply | Power supply inputs to the core of the device. |
| $\mathrm{V}_{\text {SS }}$ | $\mathrm{V}_{\text {SS }}$ | Ground | Ground for the core of the device. |
| $V_{\text {DDQ }}$ | $\mathrm{V}_{\text {DDQ }}$ | I/O Power Supply | Power supply for the I/O circuitry. |
| $\mathrm{V}_{\text {SSQ }}$ | $\mathrm{V}_{\text {SSQ }}$ | I/O Ground | Ground for the I/O circuitry. |
| MODE | MODE | InputStatic | Selects Burst Order. When tied to GND selects linear burst sequence. When tied to $\mathrm{V}_{\mathrm{DDQ}}$ or left floating selects interleaved burst sequence. This is a strap pin and should remain static during device operation. Mode Pin has an internal pull-up. |
| NC | NC |  | No Connects. |

## Introduction

## Functional Overview

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise ( $\mathrm{T}_{\mathrm{CO}}$ ) is 2.6 ns (250-MHz device).
The CY7C1347F supports secondary cache in systems utilizing either a linear or interleaved burst sequence. The linear burst sequence is suited for processors that utilize a linear burst sequence. The burst order is user selectable, and is determined by sampling the MODE input. Accesses can be initiated with either the Address Strobe from Processor ( $\overline{\mathrm{ADSP}}$ ) or the Address Strobe from Controller ( $\overline{\mathrm{ADSC}}$ ). Address advancement through the burst sequence is controlled by the ADV input. A two-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.
Byte write operations are qualified with the Byte Write Enable (BWE) and Byte Write Select ( $\overline{B W}_{[A: D]}$ ) inputs. A Global Write Enable ( $\overline{\mathrm{GW}}$ ) overrides all byte write inputs and writes data to all four bytes. All writes are simplified with on-chip synchronous self-timed write circuitry.
Three synchronous Chip Selects ( $\left.\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}\right)$ and an asynchronous Output Enable ( $\overline{\mathrm{OE}}$ ) provide for easy bank selection and output three-state control. $\overline{\text { ADSP }}$ is ignored if $\mathrm{CE}_{1}$ is HIGH.

## Single Read Accesses

This access is initiated when the following conditions are satisfied at clock rise: (1) $\overline{\text { ADSP }}$ or ADSC is asserted LOW, (2) $\overline{C E}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}$ are all asserted active, and (3) the write signals (GW, BWE) are all deasserted HIGH. ADSP is ignored if $\mathrm{CE}_{1}$ is HIGH. The address presented to the address inputs ( $\mathrm{A}_{[16: 0]}$ ) is stored into the address advancement logic and the Address Register while being presented to the memory core. The corresponding data is allowed to propagate to the input of the Output Registers. At the rising edge of the next clock the data is allowed to propagate through the Output Register and onto the data bus within $2.6 \mathrm{~ns}(250-\mathrm{MHz}$ device) if $\overline{\mathrm{OE}}$ is active LOW. The only exception occurs when the SRAM is emerging from a deselected state to a selected state, its outputs are always three-stated during the first cycle of the access. After the first cycle of the access, the outputs are controlled by the $\overline{\mathrm{OE}}$ signal. Consecutive single read cycles are supported. Once the SRAM is deselected at clock rise by the chip select and either $\overline{\text { ADSP }}$ or $\overline{\text { ADSC }}$ signals, its output will three-state immediately.

## Single Write Accesses Initiated by $\overline{A D S P}$

This access is initiated when both of the following conditions are satisfied at clock rise: (1) ADSP is asserted LOW, and (2) $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}$ are all asserted active. The address presented to $A_{[16: 0]}$ is loaded into the Address Register and the address advancement logic while being delivered to the RAM core. The write signals ( $\overline{\mathrm{GW}}, \overline{\mathrm{BWE}}$, and $\overline{\mathrm{BW}}_{[\mathrm{A}: D]}$ ) and $\overline{\mathrm{ADV}}$ inputs are ignored during this first cycle.
$\overline{\mathrm{ADSP}}$-triggered write accesses require two clock cycles to complete. If $\overline{\mathrm{GW}}$ is asserted LOW on the second clock rise, the data presented to the DQs and DQPs inputs is written into the
corresponding address location in the RAM core. If $\overline{\mathrm{GW}}$ is HIGH, then the write operation is controlled by BWE and $\overline{B W}_{[A: D]}$ signals. The CY7C1347F provides byte write capability that is described in the Write Cycle Description table. Asserting the Byte Write Enable input (BWE) with the selected Byte Write ( $\mathrm{BW}_{[\mathrm{A}: \mathrm{D}]}$ ) input will selectively write to only the desired bytes.
Bytes not selected during a byte write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the write operations.
Because the CY7C1347F is a common I/O device, the Output Enable ( $\overline{\mathrm{OE}})$ must be deasserted HIGH before presenting data to the DQs and DQPs inputs. Doing so will three-state the output drivers. As a safety precaution, DQs and DQPs are automatically three-stated whenever a write cycle is detected, regardless of the state of $\overline{\mathrm{OE}}$.

## Single Write Accesses Initiated by $\overline{A D S C}$

$\overline{\text { ADSC }}$ write accesses are initiated when the following conditions are satisfied: (1) $\overline{\text { ADSC }}$ is asserted LOW, (2) ADSP is deasserted HIGH, (3) $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}$ are all asserted active, and (4) the appropriate combination of the write inputs (GW, $\overline{\mathrm{BWE}}$, and $\overline{\mathrm{BW}}_{\left[\mathrm{A}: D_{]}\right)}$are asserted active to conduct a write to the desired byte(s). ADSC-triggered write accesses require a single clock cycle to complete. The address presented to $\mathrm{A}_{[16: 0]}$ is loaded into the address register and the address advancement logic while being delivered to the RAM core. The $\overline{\text { ADV }}$ input is ignored during this cycle. If a global write is conducted, the data presented to the DQs and DQPs is written into the corresponding address location in the RAM core. If a byte write is conducted, only the selected bytes are written. Bytes not selected during a byte write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the write operations.
Because the CY7C1347F is a common I/O device, the Output Enable ( $\overline{\mathrm{OE}}$ ) must be deasserted HIGH before presenting data to the DQs and DQPs inputs. Doing so will three-state the output drivers. As a safety precaution, DQs and DQPs are automatically three-stated whenever a write cycle is detected, regardless of the state of $\overline{\mathrm{OE}}$.

## Burst Sequences

The CY7C1347F provides a two-bit wraparound counter, fed by $A_{[1: 0]}$, that implements either an interleaved or linear burst sequence. The interleaved burst sequence is designed specifically to support Intel Pentium applications. The linear burst sequence is designed to support processors that follow a linear burst sequence. The burst sequence is user-selectable through the MODE input.
Asserting $\overline{\text { ADV }}$ LOW at clock rise will automatically increment the burst counter to the next address in the burst sequence. Both read and write burst operations are supported.

## Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. $\overline{\mathrm{CE}}_{1}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}, \overline{\mathrm{ADSP}}$, and ADSC must remain inactive for the duration of $\mathrm{t}_{\text {ZZREC }}$ after the ZZ input returns LOW.

## Interleaved Burst Sequence

## Notes:

2. $\mathrm{X}=$ "Don't Care." H = Logic HIGH, L = Logic LOW
3. $\overline{W R I T E}=L$ when any one or more Byte Write enable signals $\left(\overline{B W}_{A}, \overline{\mathrm{BW}}_{\mathrm{B}}, \overline{\mathrm{BW}}_{\mathrm{C}}, \overline{\mathrm{BW}}_{\mathrm{D}}\right)$ and $\overline{\mathrm{BWE}}=\mathrm{L}$ or $\overline{\mathrm{GW}}=\mathrm{L}$. $\overline{\mathrm{WRIIE}}=\mathrm{H}$ when all Byte write enable signals $\left(\mathrm{BW}_{\mathrm{A}}, \mathrm{BW}_{\mathrm{B}}, \mathrm{BW}_{\mathrm{C}}, \mathrm{BW}_{\mathrm{D}}\right), \mathrm{BWE}, \mathrm{GW}=\mathrm{H}$.
4. The DQ pins are controlled by the current cycle and the $\overline{O E}$ signal. $\overline{O E}$ is asynchronous and is not sampled with the clock.
5. The SRAM always initiates a read cycle when ADSP asserted, regardless of the state of GW, BWE, or BW ${ }_{[A: D]}$. Writes may occur only on subsequent clocks after the ADSP or with the assertion of ADSC. As a result, OE must be driven HIGH prior to the start of the write cycle to allow the outputs to three-state. OE is a don't care for the remainder of the write cycle.
6. $\overline{\mathrm{OE}}$ is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle all data bits are three-state when $\overline{\mathrm{OE}}$ is inactive or when the device is deselected, and all data bits behave as output when $\overline{\mathrm{OE}}$ is active (LOW)

## Notes:

11. This part has a voltage regulator internally; $t_{P O W E R}$ is the time that the power needs to be supplied above $V_{D D}($ minimum $)$ initially before a read or write operation can be initiated.
12. $\mathrm{t}_{\mathrm{CHZ}}, \mathrm{t}_{\mathrm{CLZ}}, \mathrm{t}_{\mathrm{OELZ}}$, and $\mathrm{t}_{\mathrm{OEHZ}}$ are specified with AC test conditions shown in part (b) of AC Test Loads. Transition is measured $\pm 200 \mathrm{mV}$ from steady-state voltage. 13. At any given voltage and temperature, $\mathrm{t}_{\mathrm{OEHZ}}$ is less than $\mathrm{t}_{\mathrm{OELZ}}$ and $\mathrm{t}_{\mathrm{CHZ}}$ is less than $\mathrm{t}_{\mathrm{CLZ}}$ to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions.
13. This parameter is sampled and not $100 \%$ tested.
14. Timing references level is 1.5 V when $\mathrm{V}_{\mathrm{DDQ}}=3.3 \mathrm{~V}$ and is 1.25 V when $\mathrm{V}_{\mathrm{DDQ}}=2.5 \mathrm{~V}$ on all data sheets.
15. Test conditions shown in (a) of AC Test Loads unless otherwise noted.
