

288Mb SIO Reduced Latency (RLDRAM[®]) II

MT49H16M18C

For the latest data sheet, refer to Micron's Web site: www.micron.com/rldram

Features

- 400 MHz DDR operation (800 Mb/s/pin data rate)
- Organization
 - 16 Meg x 18 separate I/O
 - 8 banks
- Cyclic bank switching for maximum bandwidth
- Reduced cycle time (20ns at 400 MHz)
- Nonmultiplexed addresses (address multiplexing option available)
- SRAM-type interface
- READ latency, row cycle time, and burst sequence length
- Balanced READ and WRITE latencies in order to optimize data bus utilization
- Data mask for WRITE commands
- Differential input clocks (CK, CK#)
- Differential input data clocks (DKx, DKx#)
- On-chip DLL generates CK edge-aligned data and output data clock signals
- Data valid signal (QVLD)
- 32ms refresh (8K refresh for each bank; 64K refresh command must be issued in total each 32ms)
- 144-ball FBGA package
- HSTL I/O (1.5V or 1.8V nominal)
- 25Ω–60Ω matched impedance outputs
- 2.5V VEXT, 1.8V VDD, 1.5V or 1.8V VDDQ I/O
- On-die termination (ODT) RTT

Figure 1: 144-Ball FBGA

General Description

The Micron[®] 288Mb reduced latency DRAM (RLDRAM[®]) II is a high-speed memory device designed for high bandwidth data storage—telecommunications, networking, and cache applications, etc. The chip's 8-bank architecture is optimized for high speed and achieves a peak bandwidth of 28.8 Gb/s, using two separate 18-bit double data rate (DDR) parts and a maximum system clock of 400 MHz.

The DDR separate I/O interface transfers two 18-bit wide data word per clock cycle at the I/O balls. The read port has dedicated data outputs to support READ operations, while the write port has dedicated input balls to support WRITE operations. Output data is referenced to the free-running output data clock. This architecture eliminates the need for high-speed bus turnaround.

Commands, addresses, and control signals are registered at every positive edge of the differential input clock, while input data is registered at both positive and negative edges of the input data clock(s).

Read and write accesses to the RLD RAM are burst-oriented. The burst length is programmable from 2, 4, or 8 by setting the mode register.

The device is supplied with 2.5V and 1.8V for the core and 1.5V or 1.8V for the output drivers.

Bank-scheduled refresh is supported with row address generated internally.

A standard μ BGA 144-ball package is used to enable ultra high-speed data transfer rates and a simple upgrade path from former products.

Functional Block Diagram

Figure 2: 16 Meg x 18

- Notes:
1. When the BL = 8 setting is used, A18 and A19 are "Don't Care."
 2. When the BL = 4 setting is used, A19 is "Don't Care."

- Notes:
1. Reserved for future use. This may optionally be connected to GND.
 2. Reserved for future use. This signal is internally connected and has parasitic characteristics of an address input signal. This may optionally be connected to GND.
 3. No function. This signal is internally connected and has parasitic characteristics of a clock input signal.

Table 3: Ball Descriptions

Symbol	Type	Description
CK, CK#	Input	Input clock: CK and CK# are differential clock inputs. Addresses and commands are latched on the rising edge of CK. CK# is ideally 180 degrees out of phase with CK.
CS#	Input	Chip select: CS# enables the command decoder when LOW and disables it when HIGH. When the command decoder is disabled, new commands are ignored, but internal operations continue.
WE#, REF#	Input	Command inputs: Sampled at the positive edge of CK, WE#, and REF# define (together with CS#) the command to be executed.
A[0:20]	Input	Address inputs: A[0:20] define the row and column addresses for READ and WRITE operations. During a MODE REGISTER SET, the address inputs define the register settings. They are sampled at the rising edge of CK. In the x18 configuration, A[20] is reserved for address expansion. These expansion addresses can be treated as address inputs, but they do not affect the operation of the device.
A21	-	Reserved for future use. This signal is internally connected and can be treated as an address input.
A22	-	Reserved for future use. This signal is not connected and may be connected to ground.
DKx, DKx#	Input	Input data clock: DKx and DKx# are the differential input data clocks. All input data is referenced to both edges of DK. DK# is ideally 180 degrees out of phase with DK. D0–D17 are referenced to DK0 and DK0#.
DM	Input	Input data mask: The DM signal is the input mask signal for WRITE data. Input data is masked when DM is sampled HIGH, along with the WRITE input data. DM is sampled on both edges of DK.
BA[0:2]	Input	Bank address inputs: Select to which internal bank a command is being applied.
D0–D17	Input	Data input: The D signals form the 18-bit input data bus. During WRITE commands, the data is referenced to both edges of DK.
Q0–Q17	Output	Data output: The Q signals form the 18-bit output data bus. During READ commands, the data is referenced to both edges of QK.
QKx, QKx#	Output	Output data clocks: QKx and QKx# are opposite polarity, output data clocks. During READs, they are free running and edge-aligned with data output from the RLD RAM. QKx# is ideally 180 degrees out of phase with QKx. QK0 and QK0# are aligned with Q0–Q8 and QK1 and QK1# are aligned with Q9–Q17. Consult the RLD RAM II Design Guide for more details.
QVLD	Output	Data valid: The QVLD indicates valid output data. QVLD is edge-aligned with QKx and QKx#.
TMS TDI	Input	IEEE 1149.1 test inputs: These balls may be left as no connects if the JTAG function is not used in the circuit
TCK	Input	IEEE 1149.1 clock input: This ball must be tied to Vss if the JTAG function is not used in the circuit.
TDO	Output	IEEE 1149.1 test output: JTAG output.
ZQ	Input/Output	External impedance [25Ω–60Ω]: This signal is used to tune the device outputs to the system data bus impedance. Q output impedance is set to $0.2 \times RQ$, where RQ is a resistor from this signal to ground. Connecting ZQ to GND invokes the minimum impedance mode. Connecting ZQ to VDD invokes the maximum impedance mode. Refer to Figure 8 on page 16 to activate this function.
VREF	Input	Input reference voltage: Nominally VDDQ/2. Provides a reference voltage for the input buffers.
VEXT	Supply	Power supply: 2.5V nominal. See Table 21 for range.
VDD	Supply	Power supply: 1.8V nominal. See Table 21 for range.
VDDQ	Supply	DQ power supply: Nominally, 1.5V or 1.8V. Isolated on the device for improved noise immunity. Table 21 for range.
Vss	Supply	Ground.

Table 3: Ball Descriptions (continued)

Symbol	Type	Description
V _{SSQ}	Supply	DQ ground: Isolated on the device for improved noise immunity.
V _{TT}	Supply	Power supply: Isolated termination supply. Nominally, V _{DDQ} /2. See Table 21 for range.
NF	-	No function: These balls may be connected to ground.
DNU	-	Do not use: These balls may be connected to ground.

Commands

According to the functional signal description, the following command sequences are possible. All input states or sequences not shown are illegal or reserved. All command and address inputs must meet setup and hold times around the rising edge of CK.

Table 4: Address Widths at Different Burst Lengths

Burst Length	Configuration
	x18
BL = 2	19:0
BL = 4	18:0
BL = 8	17:0

Table 5: Command Table
Note 1

Operation	Code	CS#	WE#	REF#	A(20:0)	B(2:0)	Notes
Device DESELECT/NO OPERATION	DESEL/NOP	H	X	X	X	X	
MRS: MODE REGISTER SET	MRS	L	L	L	OPCODE	X	2
READ	READ	L	H	H	A	BA	3
WRITE	WRITE	L	L	H	A	BA	3
AUTO REFRESH	AREF	L	H	L	X	BA	

- Notes:
1. X represents a "Don't Care"
H represents a logic HIGH
L represents a logic LOW
A represents a valid address
BA represents a valid bank address.
 2. Only A[17:0] are used for the MRS command.
 3. See Table 4.

Table 6: Description of Commands

Command	Description
DESEL/NOP ¹	The NOP command is used to perform a no operation to the RLDRAM, which essentially deselects the chip. Use the NOP command to prevent unwanted commands from being registered during idle or wait states. Operations already in progress are not affected. Output values depend on command history.
MRS	The mode register is set via the address inputs A(17:0). See Figure 8 on page 16 for further information. The MRS command can only be issued when all banks are idle and no bursts are in progress.
READ	The READ command is used to initiate a burst read access to a bank. The value on the BA(2:0) inputs selects the bank, and the address provided on inputs A(20:0) selects the data location within the bank.
WRITE	The WRITE command is used to initiate a burst write access to a bank. The value on the BA(2:0) inputs selects the bank, and the address provided on inputs A(20:0) selects the data location within the bank. Input data appearing on the DS is written to the memory array subject to the DM input logic level appearing coincident with the data. If the DM signal is registered LOW, the corresponding data will be written to memory. If the DM signal is registered HIGH, the corresponding data inputs will be ignored (i.e., this part of the data word will not be written).
AREF	The AREF is used during normal operation of the RLDRAM to refresh the memory content of a bank. The command is nonpersistent, so it must be issued each time a refresh is required. The value on the BA(2:0) inputs selects the bank. The refresh address is generated by an internal refresh controller, effectively making each address bit a "Don't Care" during the AREF command. The RLDRAM requires 64K cycles at an average periodic interval of 0.49 μ s ² (MAX). To improve efficiency, eight AREF commands (one for each bank) can be posted to the RLDRAM at periodic intervals of 3.9 μ s ³ .

- Notes:
1. When the chip is deselected, internal NOP commands are generated and no commands are accepted.
 2. Actual refresh is 32ms/8K/8 = 0.488 μ s.
 3. Actual refresh is 32ms/8k = 3.90 μ s.

Table 7: AC Electrical Characteristics

Note: 1

Description	Symbol	-25		-33		-5		Units	Notes
		Min	Max	Min	Max	Min	Max		
Clock									
Clock cycle time	t_{CK}, t_{DK}	2.5	5.7	3.3	5.7	5.0	5.7	ns

Clock HIGH time	t_{CKH}, t_{DKH}	0.45	0.55	0.45	0.55	0.45	0.55	t_{CK}	
Clock LOW time	t_{CKL}, t_{DKL}	0.45	0.55	0.45	0.55	0.45	0.55	t_{CK}	
Clock to input data clock	t_{CKDK}	-0.3	0.5	-0.3	1.0	-0.3	1.5	ns	
Mode register set cycle time to any command	t_{MRSC}	6		6		6		t_{CK}	
Setup Times									
Address/command and input setup time	t_{AS}/t_{CS}	0.4		0.5		0.8		ns	
Data-in and data mask to DK setup time	t_{DS}	0.25		0.3		0.4		ns	
Hold Times									
Address/command and input hold time	t_{AH}/t_{CH}	0.4		0.5		0.8		ns	
Data-in and data mask to DK hold time	t_{DH}	0.25		0.3		0.4		ns	
Data and Data Strobe									
Output data clock HIGH time	t_{QKH}	0.9	1.1	0.9	1.1	0.9	1.1	t_{CKH}	
Output data clock LOW time	t_{QKL}	0.9	1.1	0.9	1.1	0.9	1.1	t_{CKL}	
QK edge to clock edge skew	t_{CKQK}	-0.25	0.25	-0.3	0.3	-0.5	0.5	ns	
QK edge to output data edge	t_{QKQ0}, t_{QKQ1}	-0.2	0.2	-0.25	0.25	-0.3	0.3	ns	3
QK edge to any output data edge	t_{QKQ}	-0.3	0.3	-0.35	0.35	-0.4	0.4	ns	4
QK edge to QVLD	t_{QKVLD}	-0.3	0.3	-0.35	0.35	-0.4	0.4	ns	

- Notes:
1. All timing parameters are measured relative to the crossing point of CK/CK#, DK/DK# and to the crossing point with VREF of the command, address, and data signals.
 2. Clock phase jitter is the variance from clock rising edge to the next expected clock rising edge.
 3. t_{QKQ0} is referenced to Q0–Q8 in x18.
 t_{QKQ1} is referenced to Q9–Q17 in x18.
 4. t_{QKQ} takes into account the skew between any QKx and any Q.

Figure 3: Clock/Input Data Clock Command/Address Timings

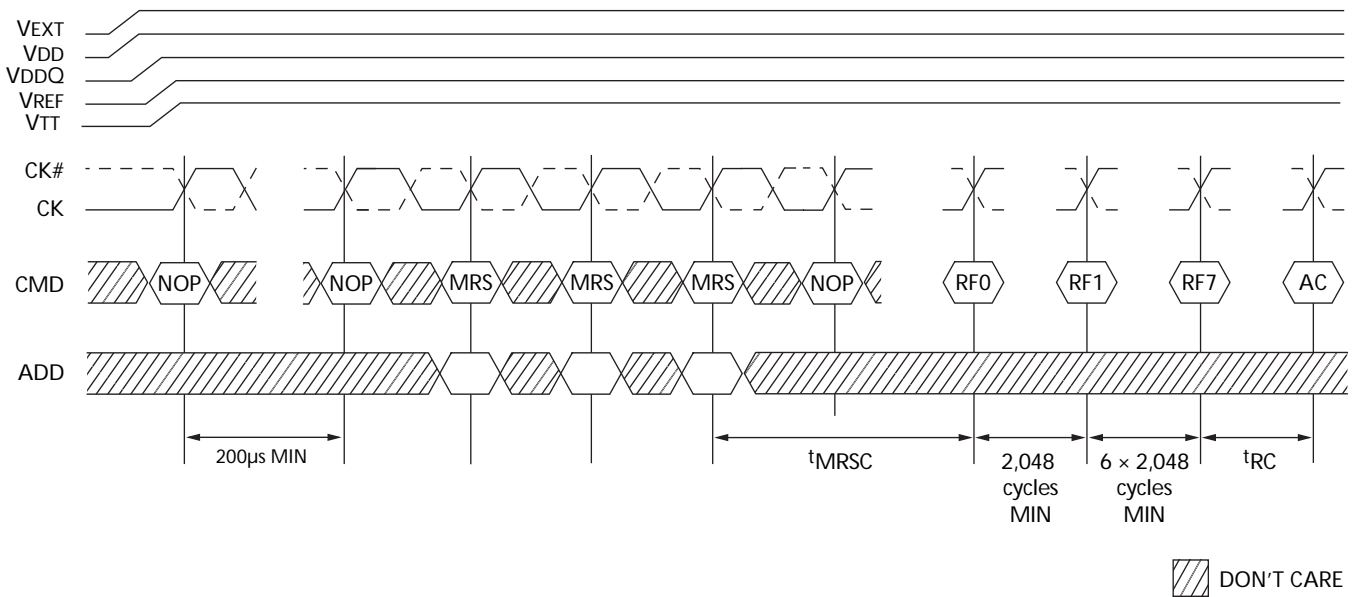

Initialization

The RLD RAM must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operations or permanent damage to the device.

The following sequence is used for power-up:

1. Apply power (VEXT, VDD, VDDQ, VREF, VTT) and start clock as soon as the supply voltages are stable. Apply VDD and VEXT before or at the same time as VDDQ. Apply VDDQ before or at the same time as VREF and VTT. Although there is no timing relation between VEXT and VDD, the chip starts the power-up sequence only after both voltages are at their nominal levels. The pad supply must not be applied before the core supplies. Maintain all remaining balls in NOP conditions.
2. Maintain stable conditions for 200 μ s (MIN).
3. Issue three MRS commands: two dummies plus one valid MRS.
4. t_{MRSC} after the valid MRS, issue 8 AUTO REFRESH commands, one on each bank and separated by 2,048 cycles. Initial bank refresh order does not matter.
5. After t_{RC} , the chip is ready for normal operation.

Figure 4: Power-Up Sequence

Note: MRS: MRS command
RFx: REFRESH bank x
AC: Any command.

Programmable Impedance Output Buffer

The RLD RAM II is equipped with programmable impedance output buffers. This allows a user to match the driver impedance to the system. To adjust the impedance, an external precision resistor (RQ) is connected between the ZQ ball and VSS. The value of the resistor must be five times the desired impedance. For example, a 300Ω resistor is required for an output impedance of 60Ω. To ensure that output impedance is one fifth the value of RQ (within 15 percent), the range of RQ is 125Ω to 300Ω.

Output impedance updates may be required because, over time, variations may occur in supply voltage and temperature. The device samples the value of RQ. An impedance update is transparent to the system and does not affect device operation. All data sheet timing and current specifications are met during an update.

Clock Considerations

The RLD RAM II utilizes internal delay-locked loops for maximum output, data valid windows. It can be placed into a stopped-clock state to minimize power with a modest restart time of 1,024 cycles.

Table 8: Clock Input Operating Conditions

Notes [1]–[8]

Parameter/Condition	Symbol	Min	Max	Units	Notes
Clock input voltage level; CK and CK#	V _{IN} (DC)	-0.3	V _{DDQ} + 0.3	V	
Clock input differential voltage; CK and CK#	V _{ID} (DC)	0.2	V _{DDQ} + 0.6	V	[9]
Clock input differential voltage; CK and CK#	V _{ID} (AC)	0.4	V _{DDQ} + 0.6	V	[9]
Clock input crossing point voltage; CK and CK#	V _{IX} (AC)	V _{DDQ} /2 - 0.15	V _{DDQ} /2 + 0.15	V	[10]

Figure 5: Clock Input

- Notes:
1. DKx and DKx# have the same requirements as CK and CK#.
 2. All voltages referenced to V_{SS}.
 3. Tests for AC timing, I_{DD}, and electrical AC and DC characteristics may be conducted at nominal reference/supply voltage levels, but the related specifications and device operations are tested for the full voltage range specified.
 4. Outputs (except for I_{DD} measurements) measured with equivalent load.
 5. AC timing and I_{DD} tests may use a V_{IL}-to-V_{IH} swing of up to 1.5V in the test environment, but input timing is still referenced to V_{REF} (or to the crossing point for CK/CK#), and parameter specifications are tested for the specified AC input levels under normal use conditions. The minimum slew rate for the input signals used to test the device is 2 V/ns in the range between V_{IL(AC)} and V_{IH(AC)}.
 6. The AC and DC input level specifications are as defined in the HSTL Standard (i.e., the receiver will effectively switch as a result of the signal crossing the AC input level, and will remain in that state as long as the signal does not ring back above [below] the DC input LOW [HIGH] level).
 7. The CK/CK# input reference level (for timing referenced to CK/CK#) is the point at which CK and CK# cross. The input reference level for signals other than CK/CK# is V_{REF}.
 8. CK and CK# input slew rate must be ≥ 2 V/ns (≥4 V/ns if measured differentially).
 9. V_{ID} is the magnitude of the difference between the input level on CK and the input level on CK#.
 10. The value of V_{Ix} is expected to equal V_{DDQ}/2 of the transmitting device and must track variations in the DC level of the same.
 11. CK and CK# must cross within this region.
 12. CK and CK# must meet at least V_{ID(DC)} MIN when static and centered around V_{DDQ}/2.
 13. Minimum peak-to-peak swing.

MODE REGISTER SET Command (MRS)

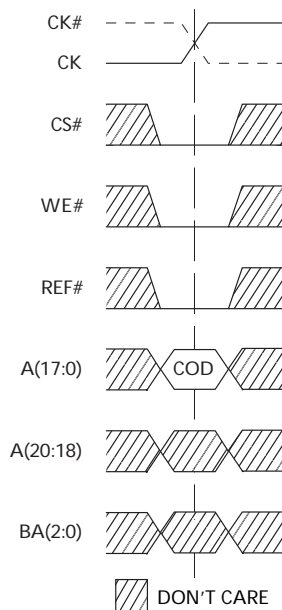

The mode register stores the data for controlling the operating modes of the memory. It programs the RLDRAM configuration, burst length, test mode, and I/O options. During a MRS command, the address inputs A(17:0) are sampled and stored in the mode register. ^tMRSC must be met before any command can be issued to the RLDRAM. The mode register may be set at any time during device operation. However, any pending operations are not guaranteed to successfully complete. See the RLDRAM II design guide for more details.

Figure 6: Mode Register Set Timing

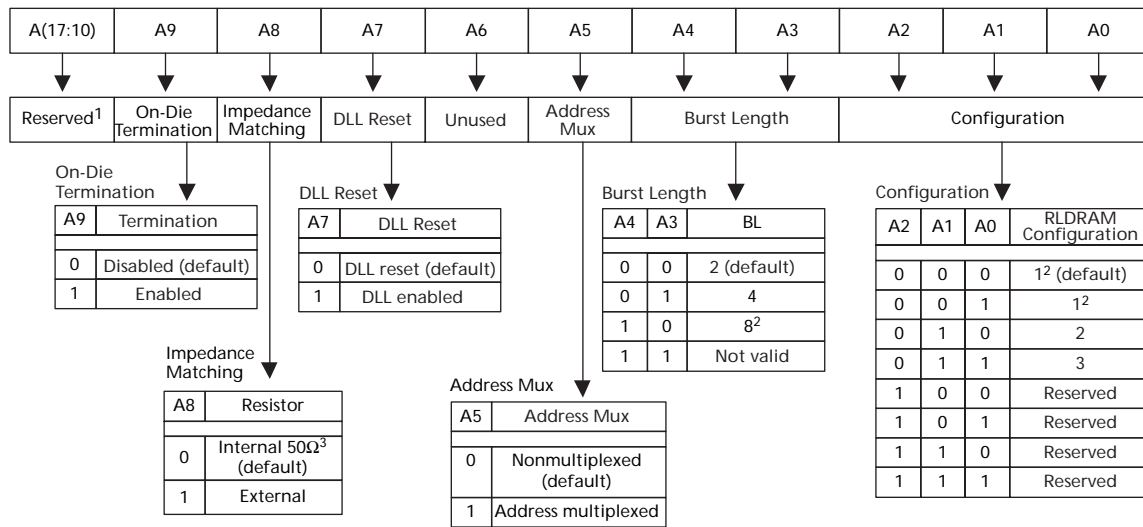

Note: MRS: MRS command
 AC: any command.

Figure 7: Mode Register Set

Note: COD: code to be loaded into the register.

Figure 8: Mode Register Bit Map

- Notes:
1. Bits A(17:10) *must* be set to zero.
 2. BL = 8 is not available for configuration 1.
 3. ±15% temperature variation.

Configuration Table

Table 9 shows, for different operating frequencies, the different RLD RAM configurations that can be programmed into the mode register. The READ and WRITE latency (^tRL and ^tWL) values along with the row cycle times (^tRC) are shown in clock cycles as well as in nanoseconds.

The shaded areas correspond to configurations that are not allowed.

Table 9: RLD RAM Configuration Table

Frequency	Symbol	Configuration			Unit
		1 ¹	2	3	
	^t RC	4	6	8	cycles
	^t RL	4	6	8	cycles
	^t WL	5	7	9	cycles
400 MHz	^t RC			20.0	ns
	^t RL			20.0	ns
	^t WL			22.5	ns
300 MHz	^t RC		20.0	26.7	ns
	^t RL		20.0	26.7	ns
	^t WL		23.3	30.0	ns

	^t WL	25.0	35.0	45.0	ns

- Notes:
1. BL = 8 is not available for configuration 1.

Write Basic Information

Write accesses are initiated with a WRITE command, as shown in Figure 9. Row and bank addresses are provided together with the WRITE command.

During WRITE commands, data will be registered at both edges of DK according to the programmed burst length (BL). A WRITE latency (WL) one cycle longer than the programmed READ latency (RL + 1) is present, with the first valid data registered at the first rising DK edge WL cycles after the WRITE command.

Any WRITE burst may be followed by a subsequent READ command. Figures 13 and 14 illustrate the timing requirements for a WRITE followed by a READ for bursts of two and four, respectively.

Setup and hold times for incoming D relative to the DK edges are specified as ^tDS and ^tDH. The input data is masked if the corresponding DM signal is HIGH. The setup and hold times for data mask are also ^tDS and ^tDH.

DON'T CARE

Read Basic Information

Read accesses are initiated with a READ command, as shown in Figure 15. Row and bank addresses are provided with the READ command.

During READ bursts, the memory device drives the read data edge-aligned with the QK signal. After a programmable read latency, data is available at the outputs. The data valid signal indicates that valid data will be present in the next half clock cycle.

The skew between QK and the crossing point of CK is specified as t_{CKQK} . t_{QKQ0} is the skew between QK0 and the last valid data edge considered over all the data generated at the Q signals. t_{QKQ1} is the skew between QK1 and the last valid data edge considered over all the data generated at the Q signals. t_{QKQx} is derived at each QKx clock edge and is not cumulative over time. t_{QKQ} is the maximum of t_{QKQ0} and t_{QKQ1} .

After completion of a burst, assuming no other commands have been initiated, output data (Q) will go High-Z. Back-to-back READ commands are possible, producing a continuous flow of output data.

The data valid window is derived from each QK transition and is defined as:
 $\text{MIN}(t_{QKH}, t_{QKL}) - 2(t_{QKQ} [\text{MAX}])$.

Any READ burst may be followed by a subsequent WRITE command. Figures 19 and 20 on page 23 illustrate the timing requirements for a READ followed by a WRITE.

Figure 15: READ Command

Note: A: address
BA: bank address.

Figure 16: Basic READ Burst Timing

- Notes:
1. Minimum data valid window can be expressed as $\text{MIN}(t_{QKH}, t_{QKL}) - 2 \times t_{QKQx} (\text{MAX})$.
 2. t_{QKQ0} is referenced to Q0–Q8 in x18.
 t_{QKQ1} is referenced to Q9–Q17 in x18.
 3. t_{QKQ} takes into account the skew between any QKx and any Q.

AUTO REFRESH Command (AREF)

AREF is used to perform a REFRESH cycle on one row in a specific bank. The row addresses are generated by an internal refresh counter for each bank; external address balls are “Don’t Care.” The delay between the AREF command and a subsequent command to the same bank must be at least t_{RC} .

Within a period of 32ms (t_{REF}), the entire memory must be refreshed. Figure 25 illustrates an example of a continuous refresh sequence. Other refresh strategies, such as burst refresh, are also possible.

Figure 24: AUTO REFRESH Command

Note: BA: bank address.

Figure 25: AUTO REFRESH Cycle

- Notes:
1. ACx: Any command on bank x
 ARFx: Auto Refresh bank x
 ACy: Any command on different bank.
 2. t_{RC} is configuration-dependent. Refer to Table 9 on page 16.

On-Die Termination

On-die termination (ODT) is enabled by setting A9 to “1” during an MRS command. With ODT on, all the DQs and DM are terminated to V_{TT} with a resistance R_{TT}. The command, address, and clock signals are not terminated. Figure 26 below shows the equivalent circuit of a Q driver with ODT. ODTs are dynamically switched off during

READ commands and are designed to be off prior to the RLD RAM driving the bus. Similarly, ODTs are designed to switch on after the RLD RAM has issued the last piece of data. ODT at the D inputs and DM are always on.

Table 10: On-Die Termination DC Parameters

Description	Symbol	Min	Max	Units	Notes
Termination voltage	V _{TT}	0.95 × V _{REF}	1.05 × V _{REF}	V	1, 2
On-Die termination	R _{TT}	135	165	Ω	3

- Notes:
1. All voltages referenced to V_{SS} (GND).
 2. V_{TT} is expected to be set equal to V_{REF} and must track variations in the DC level of V_{REF}.
 3. The R_{TT} value is measured at 70°C T_C.

Operation with Multiplexed Addresses

In multiplexed address mode, the address can be provided to the RLDRAM in two parts that are latched into the memory with two consecutive rising clock edges. This provides the advantage that a maximum SP of 11 address balls are required to control the RLDRAM, reducing the number of balls on the controller side. The bank addresses are delivered to the RLDRAM at the same time as the write command and the first address part, Ax.

This option is available by setting bit A5 to “1” in the mode register. Once this bit is set, the READ, WRITE, and MRS commands follow the format described in Figure 30 on page 30. See Figure 32 on page 31 for the power-up sequence.

Figure 30: Command Description in Multiplexed Address Mode

- Notes:
1. Ax, Ay: Address
 BA: Bank address.
 2. The minimum setup and hold times of the two address parts are defined t_{AS} and t_{AH} .

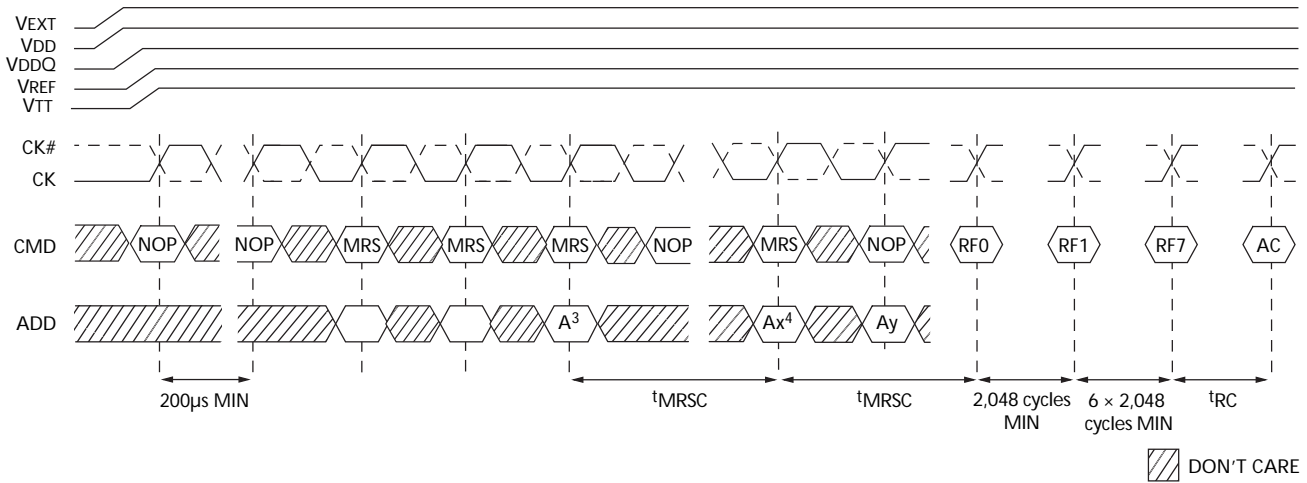

Figure 31: Mode Register Set Command in Multiplexed Address Mode

The addresses A0, A3, A4, A5, A8, and A9 must be set as follows in order to activate the mode register in the multiplexed address mode.

- Notes:
1. Bits A(17:10) must be set to zero.
 2. BL = 8 is not available for configuration 1.
 3. ±15% temperature variation.

Figure 32: Power-Up Sequence in Multiplexed Address Mode

- Notes:
1. The above sequence must be respected in order to power up the RLD RAM in the multiplexed address mode.
 2. MRS: MRS command
RFx: REFRESH bank x
AC: any command.
 3. Address A5 must be set HIGH (muxed address mode setting when RLD RAM is in normal mode of operation).
 4. Address A5 must be set HIGH (muxed address mode setting when RLD RAM is already in muxed address mode).

Address Mapping

The address mapping is described in Table 11 as a function of data width and burst length.

Table 11: Address Mapping in Multiplexed Address Mode
Note 1

Data Width	Burst Length	Ball	Addresses										
			A0 ²	A3	A4	A5 ³	A8	A9	A10	A13	A14	A17	A18
x18	BL = 2	Ax	A0	A3	A4	A5	A8	A9	A10	A13	A14	A17	A18
		Ay	X	A1	A2	X	A6	A7	A19	A11	A12	A16	A15
	BL = 4	Ax	A0	A3	A4	A5	A8	A9	A10	A13	A14	A17	A18
		Ay	X	A1	A2	X	A6	A7	X	A11	A12	A16	A15
	BL = 8	Ax	A0	A3	A4	A5	A8	A9	A10	A13	A14	A17	X
		Ay	X	A1	A2	X	A6	A7	X	A11	A12	A16	A15

- Notes:
1. X means "Don't Care."
 2. Reserved for A20 expansion in multiplexed mode.
 3. Reserved for A21 expansion in multiplexed mode.

Configuration Table

In this mode, the READ and WRITE latencies are increased by one clock cycle. The RLDRAM cycle time remains the same, as described in Table 12.

Table 12: Configuration Table In Multiplexed Address Mode

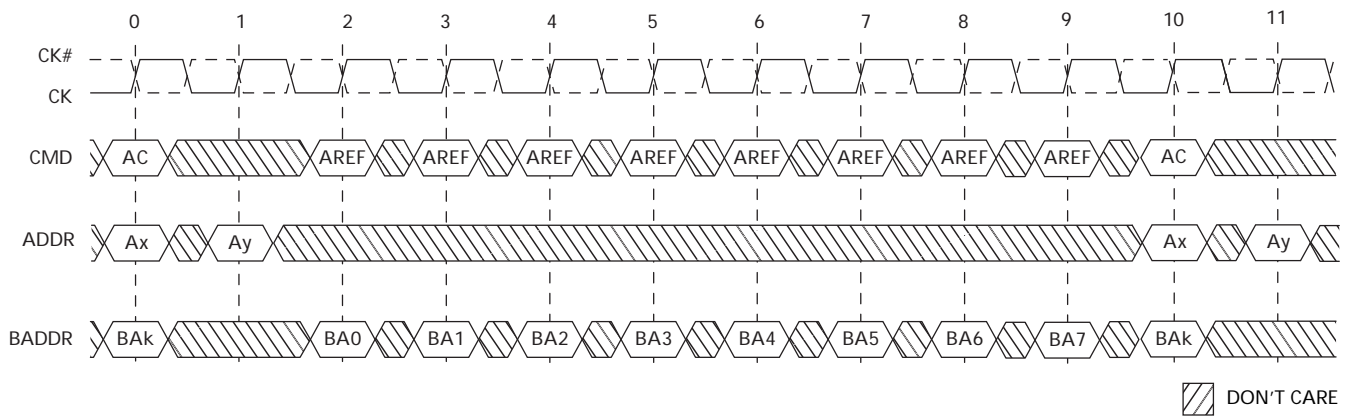

Configuration					
Frequency	Symbol	1 ¹	2	3	Unit
	t _{RC}	4	6	8	cycles
	t _{RL}	5	7	9	cycles
	t _{WL}	6	8	10	cycles
400 MHz	t _{RC}			20.0	ns
	t _{RL}			22.5	ns
	t _{WL}			25.0	ns
300 MHz	t _{RC}		20.0	26.7	ns
	t _{RL}		23.3	30.0	ns
	t _{WL}		26.7	33.3	ns
200 MHz	t _{RC}	20.0	30.0	40.0	ns
	t _{RL}	25.0	35.0	45.0	ns
	t _{WL}	35.0	40.0	50.0	ns

- Notes:
1. BL = 8 is not available for configuration 1.

Refresh Command in Multiplexed Address Mode

Similar to other commands, the refresh command is executed on the next rising clock edge when in the multiplexed address mode. However, since only bank address is required for AREF, the next command can be applied on the following clock. The operation of the AREF command and any other command is represented in Figure 33.

Figure 33: Burst Refresh Operation

Note: AREF: AUTO REFRESH
AC: Any command
Ax: First part Ax of address
Ay: Second part Ay of address
BAk: Bank k; k is chosen so that t_{RC} is met.

Note: Ax/BAk: Address Ax of bank k
Ay: Address Ay of bank k
WR: WRITE
Djk: Data k to bank j
WL: WRITE latency
Qjk: Data k to bank j
RD: READ
RL: READ latency.

IEEE 1149.1 Serial Boundary Scan (JTAG)

RLDRAM incorporates a serial boundary scan test access port (TAP). This port operates in accordance with IEEE Standard 1149.1-2001, with one exception. If the RLD_{RAM} device is being accessed with READ commands at the same time the JTAG registers are being used, the ZQ calibration updates may not occur correctly. The TAP operates using logic levels associated with the V_{DDQ} supply.

RLDRAM contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

Disabling the JTAG Feature

It is possible to operate RLD_{RAM} without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW (V_{SS}) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to V_{DD} through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state, which will not interfere with the operation of the device.

Test Access Port (TAP)

Test Clock (TCK)

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

Test Mode Select (TMS)

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this ball unconnected if the TAP is not used. The ball is pulled up internally, resulting in a logic HIGH level.

Test Data-In (TDI)

The TDI ball is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see Figure 36 on page 35. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) of any register (see Figure 37 on page 36).

Test Data-Out (TDO)

The TDO output ball is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine (see Figure 36 on page 35). The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register (see Figure 37 on page 36).

Figure 36: TAP Controller State Diagram

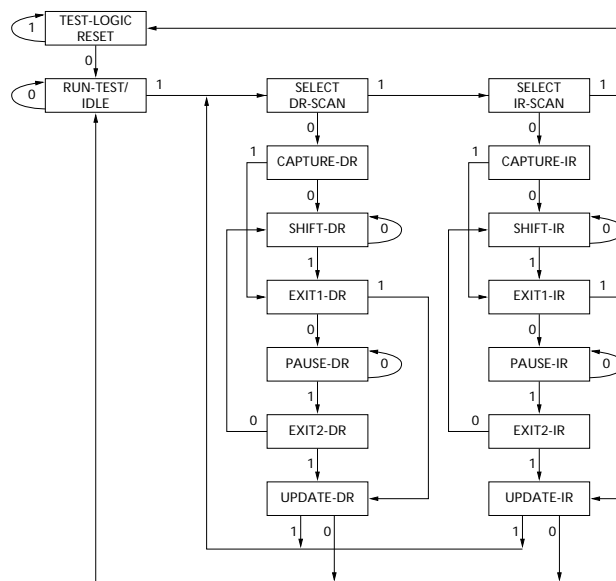

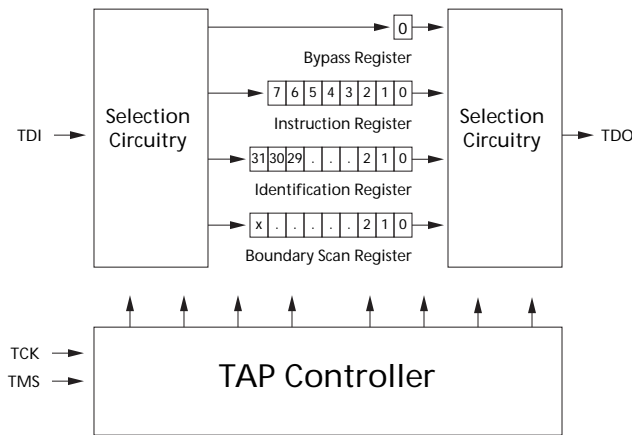

Figure 37: TAP Controller Block Diagram

Note: x = 112 for all configurations.

Performing a TAP Reset

A reset is performed by forcing TMS HIGH (VDD) for five rising edges of TCK. This reset does not affect the operation of the RLDRAM and may be performed while the RLDRAM is operating.

At power-up, the TAP is reset internally to ensure that TDO comes up in a High-Z state.

TAP Registers

Registers are connected between the TDI and TDO balls and allow data to be scanned into and out of the RLDRAM test circuitry. Only one register can be selected at a time through the instruction register. Data is serially loaded into the TDI ball on the rising edge of TCK. Data is output on the TDO ball on the falling edge of TCK.

Instruction Register

Eight-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO ball, as shown in Figure 37 on page 36. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture-IR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board-level serial test data path.

Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between the TDI and TDO balls. This allows data to be shifted through the RLDRAM with minimal delay. The bypass register is set LOW (Vss) when the BYPASS instruction is executed.

Boundary Scan Register

The boundary scan register is connected to all the input and bidirectional balls on the RLDRAM. Several balls are also included in the scan register to reserved balls. The RLDRAM has a 113-bit register.

The boundary scan register is loaded with the contents of the RAM I/O ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO balls when the controller is moved to the Shift-DR state.

The Boundary Scan Order tables (see page 42) show the order in which the bits are connected. Each bit corresponds to one of the balls on the RLDRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hard-wired into the RLDRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

TAP Instruction Set

Overview

Many different instructions (28) are possible with the eight-bit instruction register. All used combinations are listed in Table 18 on page 41. These six instructions are described in detail below. The remaining instructions are reserved and should not be used.

The TAP controller used in this RLDRAM is fully compliant to the 1149.1 convention.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO balls. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

EXTEST

The EXTEST instruction allows circuitry external to the component package to be tested. Boundary-scan register cells at output balls are used to apply a test vector, while those at input balls capture test results. Typically, the first test vector to be applied using the EXTEST instruction will be shifted into the boundary scan register using the PRELOAD instruction. Thus, during the Update-IR state of EXTEST, the output driver is turned on and the PRELOAD data is driven onto the output balls.

IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO balls and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state. The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

HIGH-Z

The HIGH-Z instruction causes the boundary scan register to be connected between the TDI and TDO. This places all RLD_{RAM} outputs into a High-Z state.

CLAMP

When the CLAMP instruction is loaded into the instruction register, the data driven by the output balls are determined from the values held in the boundary scan register.

SAMPLE/PRELOAD

When the SAMPLE/PRELOAD instruction is loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the inputs and bidirectional balls is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 50 MHz, while the RLD_{RAM} clock operates significantly faster. Because there is a large difference between the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To ensure that the boundary scan register will capture the correct value of a signal, the RLD_{RAM} signal must be stabilized long enough to meet the TAP controller's capture setup plus hold time (t_{CS} plus t_{CH}). The RLD_{RAM} clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK# captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO balls.

BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between TDI and TDO. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

Reserved for Future Use

The remaining 22 instructions are not implemented but are reserved for future use. Do not use these instructions.

31	U11	69	F11	107	G2
32	U11	70	F11	108	G3
33	T10	71	E10	109	G1
34	T10	72	E10	110	H1
35	T11	73	E11	111	H2
36	T11	74	E11	112	J2
37	R10	75	D11	113	J1
38	R10	76	D10	-	-

Notes: 1. Any unused balls that are in the order will read as the logic level applied to the ball site. If left floating, a value of "0" is returned.

Electrical Characteristics

Stresses greater than those listed in Table 20 may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 20: Absolute Maximum Ratings

Parameter	Min	Max	Units	Notes
Storage temperature	-55	+150	°C	
I/O voltage	-0.3V	VDDQ + 0.3	V	
Voltage on VEXT supply relative to Vss	-0.3	+2.8	+2.8V	
Voltage on VDD supply relative to Vss	-0.3	+2.1	V	
Voltage on VDDQ supply relative to Vss	-0.3	+2.1	V	
Junction temperature	110		°C	1

Notes: 1. Junction temperature depends upon package type, cycle time, loading, ambient temperature, and airflow.

Table 21: DC Electrical Characteristics and Operating Conditions

+0°C ≤ T_C ≤ +95°C; +1.7V ≤ VDD ≤ +1.9V, unless otherwise noted

Description	Conditions	Symbol	Min	Max	Units	Notes
Supply voltage		VEXT	2.38	2.63	V	1
Supply voltage		VDD	1.7	1.9	V	1, 4
Isolated output buffer supply		VDDQ	1.4	VDD	V	1, 4, 5
Reference voltage		VREF	0.49 × VDDQ	0.51 × VDDQ	V	1, 2, 3, 8
Termination voltage		VTT	0.95 × VREF	1.05 × VREF	V	9, 10
Input high (Logic 1) voltage		VIH	VREF + 0.1	VDDQ + 0.3	V	1, 4
Input low (Logic 0) voltage		VIL	VSSQ - 0.3	VREF - 0.1	V	1, 4
Output high current	VOH = VDDQ/2	IOH	(VDDQ/2) / (1.15 × RQ/5)	(VDDQ/2) / (0.85 × RQ/5)	mA	6, 7, 11
Output low current	VOL = VDDQ/2	IOL	(VDDQ/2) / (1.15 × RQ/5)	(VDDQ/2) / (0.85 × RQ/5)	mA	6, 7, 11
Clock input leakage current	0V ≤ VIN ≤ VDD	ILC	-5	5	μA	
Input leakage current	0V ≤ VIN ≤ VDD	ILI	-5	5	μA	
Output leakage current	0V ≤ VIN ≤ VDDQ	ILO	-5	5	μA	
Reference voltage current		IREF	-5	5	μA	

- Notes:
- All voltages referenced to Vss (GND).
 - Typically the value of VREF is expected to be 0.5 × VDDQ of the transmitting device. VREF is expected to track variations in VDDQ.
 - Peak-to-peak AC noise on VREF must not exceed ±2% VREF(DC).
 - Overshoot: VIH(AC) ≤ VDD + 0.7V for t ≤ t_{CK}/2.
Undershoot: VIL(AC) ≥ -0.5V for t ≤ t_{CK}/2.
During normal operation, VDDQ must not exceed VDD.
Control input signals may not have pulse widths less than t_{CK}/2 or operate at frequencies exceeding t_{CK} (MAX).
 - VDDQ can be set to a nominal 1.5V + 0.1V or 1.8V + 0.1V supply.
 - IOH and IOL are defined as absolute values and are measured at VDDQ/2. IOH flows from the device, IOL flows into the device.

7. If MRS bit A8 is 0, use RQ = 250Ω in the equation in lieu of presence of an external impedance matched resistor.
8. V_{REF} is expected to equal V_{DDQ}/2 of the transmitting device and to track variations in the DC level of the same. Peak-to-peak noise (non-common mode) on V_{REF} may not exceed ±2% of the DC value. Thus, from V_{DDQ}/2, V_{REF} is allowed ±2%V_{DDQ}/2 for DC error and an additional ±2%V_{DDQ}/2 for AC noise. This measurement is to be taken at the nearest V_{REF} bypass capacitor.
9. V_{TT} is expected to be set equal to V_{REF} and must track variations in the DC level of V_{REF}.
10. On-die termination may be selected using mode register bit 9 (see Figure 8 on page 16). A resistance R_{TT} from each data input signal to the nearest V_{TT} can be enabled. R_{TT} = 150Ω (±10%) at 70°C T_C.
11. For V_{OL} and V_{OH}, refer to the RLD_{RAM} II HSpice or IBIS driver models.

Table 22: AC Electrical Characteristics and Operating Conditions
+0°C ≤ T_C ≤ +95°C; +1.7V ≤ V_{DD} ≤ +1.9V, unless otherwise noted

Description	Conditions	Symbol	Min	Max	Units
Input high (Logic 1) voltage	Matched impedance mode	V _{IH}	V _{REF} + 0.2	V _{DDQ} + 0.3	V
Input low (Logic 0) voltage	Matched impedance mode	V _{IL}	V _{SSQ} - 0.3	V _{REF} - 0.2	V

Table 23: Capacitance

Description	Conditions	Symbol	Min	Max	Units
Address/control input capacitance	T _A = 25°C; f = 1 MHz	C _I	1.5	2.5	pF
Input/output capacitance (D and Q)		C _O	3.5	5.0	pF
Clock capacitance		C _{CK}	2.0	3.0	pF

Figure 39: Output Test Conditions

Figure 40: Input Waveform

Table 24: IDD Operating Conditions and Maximum Limits
 $+0^{\circ}\text{C} \leq T_c \leq +95^{\circ}\text{C}$; $+1.7\text{V} \leq V_{DD} \leq +1.9\text{V}$, unless otherwise noted

Description	Conditions	Symbol	Max			Unit
			-25	-33	-5	
Standby current	$t_{CK} = \text{Idle}$ All banks idle, no inputs toggling	ISB1 (VDD)	48	48	48	mA
		ISB1 (VEXT)	26	26	26	
Active standby current	$t_{CK} = \text{MIN}$, CS# = 1 No commands, address/data change up to once every four clock cycles	ISB2 (VDD)	288	288	288	mA
		ISB2 (VEXT)	26	26	26	
Incremental current	BL = 2, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, 1 bank active, half address changes once per t_{RC} , read followed by write sequence	IDD1 (VDD)	348	305	255	mA
		IDD1 (VEXT)	41	36	36	
Incremental current	BL = 4, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, 1 bank active, half address changes once per t_{RC} , read followed by write sequence	IDD2 (VDD)	352	319	269	mA
		IDD2 (VEXT)	48	42	42	
Incremental current	BL = 8, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, 1 bank active, half address changes once per t_{RC} , read followed by write sequence	IDD3 (VDD)	408	368	286	mA
		IDD3 (VEXT)	55	48	48	
Burst refresh current	$t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$ Cyclic bank refresh, data inputs are switching	IREF1 (VDD)	680	530	367	mA
		IREF1 (VEXT)	133	111	105	
Distributed refresh current	$t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$ Single bank refresh, half address/data toggle	IREF2 (VDD)	325	267	221	mA
		IREF2 (VEXT)	48	42	42	
Operating supply current example	BL = 2, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, cyclic bank access, half of address bits change every clock cycle, continuous data	IDD2W (VDD)	970	819	597	mA
		IDD2W (VEXT)	100	90	69	
Operating supply current example	BL = 4, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, cyclic bank access, half of address bits change every two clock cycles, continuous data	IDD4W (VDD)	779	609	439	mA
		IDD4W (VEXT)	65	55	44	
Operating supply current example	BL = 8, $t_{CK} = \text{MIN}$, $t_{RC} = \text{MIN}$, cyclic bank access, half of address bits change every four clock cycles, continuous data	IDD8W (VDD)	668	525	364	mA
		IDD8W (VEXT)	60	51	40
