

1.2-A HIGH-EFFICIENCY PWM POWER DRIVER

FEATURES

- 1.22-A DC (82% Duty Cycle) Output Current ($T_J \leq 89^\circ\text{C}$)
- 1-A DC (100% Duty Cycle) Output Current ($T_J \leq 89^\circ\text{C}$)
- Low Supply Voltage Operation from 2.7 V to 5.5 V
- High Efficiency Generates Less Heat
- Over-Temperature Protection
- Short-Circuit Protection
- PowerPAD™ SOIC and 4 × 4 mm MicroStar Junior™ Packages

APPLICATIONS

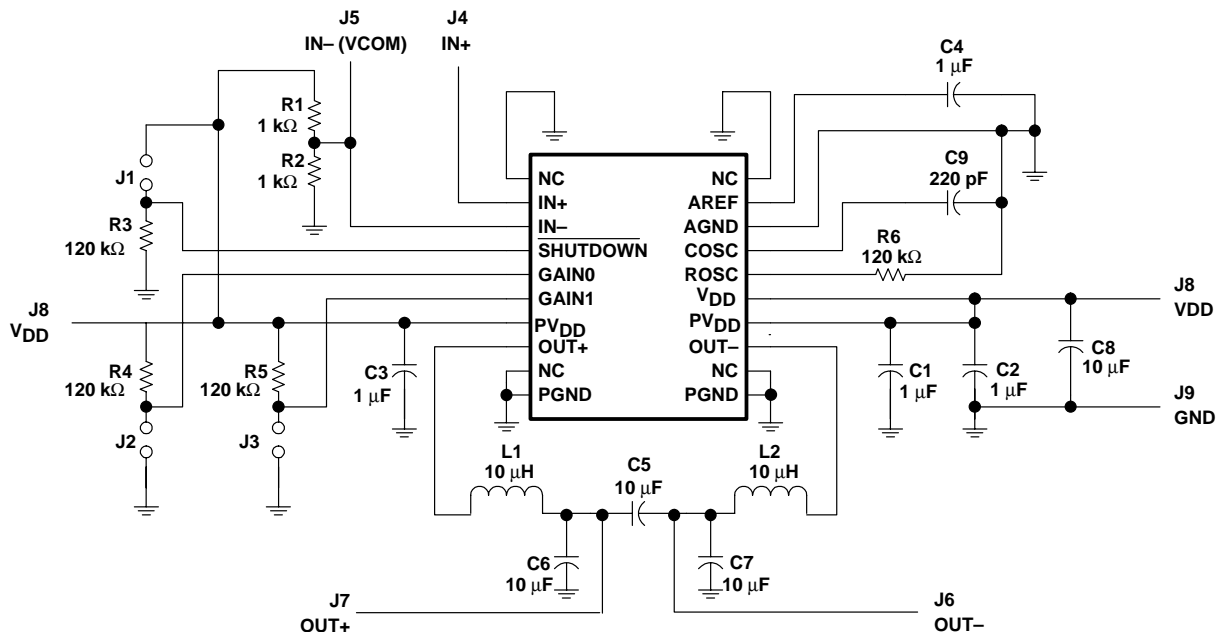

- Thermoelectric Cooler (TEC) Driver
- Laser Diode Biasing

DESCRIPTION

The DRV590 is a high-efficiency power amplifier ideal for driving a wide variety of thermoelectric cooler elements in systems powered from 2.7 V to 5.5 V. PWM operation and low output stage on-resistance significantly decrease power dissipation in the amplifier.

The DRV590 is internally protected against over temperature conditions and current overloads due to short circuits. The over temperature protection activates at a junction temperature of 190°C and will deactivate once the temperature is less than 130°C . If the overcurrent circuitry is tripped, the amplifier will automatically reset after 3–5 ms.

The gain of the DRV590 is controlled by two input terminals, GAIN1 and GAIN0. The amplifier may be configured for a gain of 6, 12, 18, and 23.5 dB.

Typical Circuit Schematic for Driving a Thermoelectric Cooler Element

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

APPLICATION INFORMATION

driving TEC elements

Below is a typical application schematic.

output filter considerations

TEC element manufacturers provide electrical specifications for maximum dc current and maximum output voltage for each particular element. The maximum ripple current, however, is typically only recommended to be less than 10%. The maximum temperature differential across the element decreases as ripple current increases and can be calculated using equation 1.

$$\Delta T = \frac{1}{(1 + N^2) \times \Delta T_{max}} \tag{1}$$

- ΔT = actual temperature differential
- ΔT_{max} = maximum temperature differential (specified by manufacturer)
- N = ratio of ripple current to dc current

According to this relationship, a 10% ripple current reduces the maximum temperature differential by 1%. A LC network may be used to filter the current flowing to the TEC to reduce the amount of ripple and, more importantly, protect the rest of the system from any electromagnetic interference (EMI).

APPLICATION INFORMATION

driving TEC elements (continued)

filter component selection

The LC filter may be designed from a couple of different perspectives, both of which may help estimate the overall performance of the system. The filter should be designed for the worst-case conditions during operation, which is typically when the differential output is at 50% duty cycle. The following section serves as a starting point for the design, and any calculations should be confirmed with a prototype circuit.

To simplify the design, half-circuit analysis may also be used. This should only be done if the TEC element is close to the output of the filter. Any filter should always be placed as close to the DRV590 as possible to reduce EMI.

Figure 10. LC Output Filter

Figure 11. LC Half-Circuit Equivalent

LC filter in the frequency domain

The transfer function for the second order low-pass filter in Figure 10 and Figure 11 is shown in equation 2.

$$H_{LP}(j\omega) = \frac{1}{-\left(\frac{\omega}{\omega_0}\right)^2 + \frac{1}{Q} \frac{j\omega}{\omega_0} + 1} \tag{2}$$

$$\omega_0 = \frac{1}{\sqrt{L \times 3C}}$$

Q = quality factor

ω = DRV590 differential switching frequency

For the DRV590, the differential output switching frequency is 500 kHz. The resonant frequency for the filter should be chosen to be at least one order of magnitude lower than the switching frequency. Equation 2 may then be simplified to give the following magnitude equation 3. These equations assume the use of the filter in Figure 10, which effectively triples the capacitance.

$$|H_{LP}|_{dB} = -40 \log\left(\frac{f_s}{f_o}\right) \tag{3}$$

$$f_o = \frac{1}{2\pi\sqrt{L \times 3C}}$$

f_s = 500 kHz (DRV590 differential switching frequency)

APPLICATION INFORMATION

LC filter in the frequency domain (continued)

If $L = 10 \mu\text{H}$ and $C = 10 \mu\text{F}$, the resonant frequency is 9.2 kHz, which corresponds to –69 dB of attenuation at the 500-kHz switching frequency. For $V_{\text{DD}} = 5 \text{ V}$, the amount of ripple voltage at the TEC element will be approximately 1.7 mV.

The average TEC element has a resistance of 1.5Ω , so the ripple current through the TEC is approximately 1.13 mA. At the 1-A maximum output current of the DRV590, this 1.13 mA corresponds to 0.113% ripple current, causing less than 0.0001% reduction of the maximum temperature differential of the TEC element (see equation 1).

LC filter in the time domain

The ripple current of an inductor can be calculated using equation 4. (4)

$$\Delta I_L = \frac{(V_{\text{DD}} - V_{\text{TEC}})DT_s}{L}$$

D = duty cycle (0.5 worst case)

$T_s = 1/f_s = 1/500 \text{ kHz}$

For $V_{\text{DD}} = 5 \text{ V}$, $V_{\text{TEC}} = 2.5 \text{ V}$, and $L = 10 \mu\text{H}$, the inductor ripple current is 250 mA. To calculate how much of that ripple current will flow through the TEC element, however, the properties of the filter capacitor must be considered.

For relatively small capacitors (less than $10 \mu\text{F}$) with very low equivalent series resistance (ESR, less than $10 \text{ m}\Omega$), such as ceramic capacitors, equation 5 may be used to estimate the ripple voltage on the capacitor due to the change in charge.

$$\Delta V_C = \frac{\pi^2}{2}(1-D)\left(\frac{f_o}{f_s}\right)^2 V_{\text{TEC}} \quad (5)$$

D = duty cycle

$f_s = 500 \text{ kHz}$

$$f_o = \frac{1}{2\pi\sqrt{L \times 3C}}$$

For $L = 10 \mu\text{H}$ and $C = 10 \mu\text{F}$, the cutoff frequency $f_o = 9.2 \text{ kHz}$. For a worst case duty cycle of 0.5 and $V_{\text{TEC}} = 2.5$, the ripple voltage on the capacitors is 2 mV. The ripple current may be simply calculated by dividing the ripple voltage by the TEC resistance of 1.5Ω , resulting in a ripple current through the TEC element of 1.33 mA. Note that this is similar to the value calculated using the frequency domain approach.

For larger capacitors (greater than $10 \mu\text{F}$) with relatively high ESR (greater than $100 \text{ m}\Omega$), such as electrolytic capacitors, the ESR drop dominates over the charging-discharging of the capacitor. Equation 6 can be used to estimate the ripple voltage.

$$\Delta V_C = \Delta I_L \times R_{\text{ESR}} \quad (6)$$

ΔI_L = inductor ripple current

R_{ESR} = filter capacitor ESR

For a $100\text{-}\mu\text{F}$ electrolytic capacitor, an ESR of 0.1Ω is common. If the $10\text{-}\mu\text{H}$ inductor is used, delivering 250 mA of ripple current to the capacitor (as calculated above), then the ripple voltage is 25 mV. This is over ten times that of the $10\text{-}\mu\text{F}$ ceramic capacitor, as ceramic capacitors typically have negligible ESR.

APPLICATION INFORMATION

LC filter in the time domain (continued)

For worst case conditions, the on-resistance of the output transistors has been ignored to give the maximum theoretical ripple current. In reality, the voltage drop across the output transistors will decrease the maximum V_O as the output current increases. It can be shown using equation 4 that this will decrease the inductor ripple current, and therefore the TEC ripple current.

general operation

oscillator components R_{OSC} and C_{OSC}

The onboard ramp generator requires an external resistor and capacitor to set the oscillation frequency. For proper operation, the resistor R_{OSC} should be 120 k Ω with 1% tolerance. The capacitor C_{OSC} should be a ceramic 220 pF with 10% tolerance. Both components should be grounded to AGND, which should be connected to PGND at a single point, typically where the power and ground physically connect to the printed circuit board.

AREF capacitor

The AREF terminal is the output of an internal mid-rail voltage regulator used for the on-board oscillator and ramp generator. The regulator may not be used to provide power to any additional circuitry. A 1- μ F ceramic capacitor must be connected from AREF to AGND for stability (see the *oscillator components R_{OSC} and C_{OSC}* section for AGND connection information).

gain settings

The differential output voltage may be calculated using equation 7.

$$V_O = V_{OUT+} - V_{OUT-} = A_v(V_{IN+} - V_{IN-}) \quad (7)$$

A_v is the voltage gain, which may be selected by configuring GAIN0 and GAIN1 according to the table below. The input resistance also varies with the gain setting, as shown by the typical values in Table 1. Though these values may vary by up to 30% due to process variations, the gain settings themselves vary little, as they are determined by resistor ratios.

Table 1. Gain Settings

GAIN0	GAIN1	AMPLIFIER GAIN (dB, TYPICAL)	INPUT RESISTANCE (k Ω , TYPICAL)
0	0	6	104
0	1	12	74
1	0	18	44
1	1	23.5	24

APPLICATION INFORMATION

general operation (continued)

input configuration—differential and single-ended

If a differential input is used, it should be biased around the mid-rail of the DRV590 and must not exceed the common-mode input range of the input stage (see the operating characteristics at the beginning of the data sheet).

The most common configuration employs a single-ended input. The unused input should be tied to the mid-rail, which may be simply accomplished with a resistive voltage divider. For the best performance, the resistor values chosen should be at least an order of magnitude lower than the input resistance of the DRV590 at the selected gain setting. This prevents the bias voltage at the unused input from shifting when the signal input is applied. A small ceramic capacitor should also be placed from the input to ground to filter noise and keep the voltage stable.

power supply decoupling

To reduce the effects of high-frequency transients or spikes, a small ceramic capacitor, typically 0.1 μF to 1 μF , should be placed as close to each PVDD pin of the DRV590 as possible. For bulk decoupling, a 10- μF to 100- μF tantalum or aluminum electrolytic capacitor should be placed relatively close to the DRV590.

SHUTDOWN operation

The DRV590 includes a shutdown mode that disables the outputs and places the device in a low supply current state. The SHUTDOWN pin may be controlled with a TTL logic signal. When SHUTDOWN is held high, the device operates normally. When SHUTDOWN is held low, the device is placed in shutdown. The SHUTDOWN pin must not be left floating. If the shutdown feature is unused, the pin may simply be connected to V_{DD} .

power dissipation and maximum ambient temperature

Though the DRV590 is much more efficient than traditional linear solutions, the IR drop across the on-resistance of the output transistors generates some heat in the package, which may be calculated using equation 8.

$$P_{\text{DISS}} = (I_{\text{OUT}})^2 \times r_{\text{ds(on), total}} \quad (8)$$

For example, at the maximum output current of 1.2 A through a total on-resistance of 1 Ω , the power dissipated in the package is 1.44 W.

The maximum ambient temperature can be calculated using equation 9.

$$T_{\text{A}} = T_{\text{J}}(\theta_{\text{JA}} \times P_{\text{DISS}}) \quad (9)$$

Continuing the example above, the maximum ambient temperature driving 1.2 A without exceeding 89°C junction temperature for a DRV590 in the DWP package (see the *maximum output current vs duty cycle* section) is 39°C.

maximum output current vs duty cycle

At 100% duty cycle across the load, the reliability of the DRV590 is degraded if more than 1 A is driven through the outputs. Furthermore, the junction temperature must not exceed 89°C at the maximum output current levels to prevent further degradation. However, as the duty cycle across the load decreases, the maximum allowable output current increases.

Table 2 shows the typical maximum output current, voltage across the load, and junction temperature versus duty cycle. The dissipation and junction temperatures were calculated using equations 8 and 9. The total on-resistance was assumed to be 1 Ω , the ambient temperature to be 25°C, and the θ_{JA} to be 34.1°C/W.

APPLICATION INFORMATION

maximum output current vs duty cycle (continued)

Table 2. Typical Maximum Output Specifications vs Duty Cycle ($V_{DD} = 5\text{ V}$)

DUTY CYCLE	MAX I_O (A)	MAX V_{LOAD} (V)	P_{DISS} (W)	T_J ($^{\circ}\text{C}$)
100%	1	4	1	67.6
95%	1.05	3.69	1.11	72.2
90%	1.11	3.38	1.24	77.6
85%	1.17	3.07	1.39	83.9
84%	1.19	3.01	1.42	85.3
83%	1.2	2.94	1.45	86.8
82%	1.22	2.88	1.49	88.3

At duty cycles less than 82%, the power dissipated from the theoretical maximum current flowing through the on-resistance causes the junction temperature to exceed 89°C . See Figure 9 for more details.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

PowerPAD is a trademark of Texas Instruments.

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
