Low Profile Overvoltage Protection IC with Integrated MOSFET

This device represents a new level of safety and integration by combining the NCP345 overvoltage protection circuit (OVP) with a 30 V P-channel power MOSFET. It is specifically designed to protect sensitive electronic circuitry from overvoltage transients and power supply faults. During such hazardous events, the IC quickly disconnects the input supply from the load, thus protecting the load before any damage can occur.

The OVP IC is optimized for applications that use an external AC-DC adapter or a car accessory charger to power a portable product or recharge its internal batteries. It has a nominal overvoltage threshold of 6.85 V which makes them ideal for single cell Li-Ion as well as 3/4 cell NiCD/NiMH applications.

Features

- Overvoltage Turn-Off Time of Less Than 1.0 μ s
- Accurate Voltage Threshold of 6.85 V, Nominal

PIN FUNCTION DESCRIPTIONS

Pin #	Symbol	Pin Description
1	IN	This pin senses an external voltage point. If the voltage on this input rises above the overvoltage threshold (V_{TH}), the OUT pin will be driven to within 1.0 V of V_{CC} , thus disconnecting the P-Channel Power MOSFET. The nominal threshold level is 6.85 V and this threshold level can be increased with the addition of an external resistor between IN and V_{CC} .
2	GND	Circuit Ground
3	CNTRL	This logic signal is used to control the state of OUT and turn-on/off the P-Channel Power MOSFET. A logic High results in the OUT signal being driven to within 1.0 V of V_{CC} which disconnects the FET. If this pin is not used, the input should be connected to ground.
4	DRAIN	Drain pin of the P-Channel Power MOSFET
5	SRC	Source pin of the P-Channel Power MOSFET
6	GATE	Gate pin of the P-Channel Power MOSFET
7	OUT	This signal drives the gate of a P-Channel Power MOSFET. It is controlled by the voltage level on IN or the logic state of the CNTRL input. When an overvoltage event is detected, the OUT pin is driven to within 1.0 V of V_{CC} in less than 1.0 μ sec provided that gate and stray capacitance is less than 12 nF.
8	V_{CC}	Positive Voltage supply. If V_{CC} falls below 2.8 V (nom), the OUT pin will be driven to within 1.0 V of V_{CC} , thus disconnecting the P-channel FET.
