¹ Accuracy is specified for 0 V to 7 V rms, dc or 1 kHz sine wave input with the AD536A connected as in the figure referenced.

² Error vs. crest factor is specified as an additional error for 1 V rms rectangular pulse input, pulse width = 200 μs .

³ Input voltages are expressed in volts rms, and error is expressed as a percentage of the reading.

⁴ With 2k Ω external pull-down resistor.

ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
|---|-----------------|
| Supply Voltage | |
| Dual Supply | ±18 V |
| Single Supply | +36 V |

| Thermal Resistance θ_{JA} ¹ | |
| 10-Pin Header (H-10 Package) | 150°C/W |
| 20-Terminal LCC (E-20 Package) | 95°C/W |
| 14-Lead SBDIP (D-14 Package) | 95°C/W |
| 14-Lead CERDIP (Q-14 Package) | 95°C/W |

¹ θ_{JA} is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PAD NUMBERS CORRESPOND TO PIN NUMBERS FOR THE TO-100 14-LEAD CERAMIC DIP PACKAGE.

¹BOTH PADS SHOWN MUST BE CONNECTED TO V_{IN}. THE AD536A IS AVAILABLE IN LASER-TRIMMED CHIP FORM. SUBSTRATE CONNECTED TO −V_S.

APPLICATIONS INFORMATION

TYPICAL CONNECTIONS

The AD536A is simple to connect to for the majority of high accuracy rms measurements, requiring only an external capacitor to set the averaging time constant. The standard connection is shown in Figure 6 through Figure 8. In this configuration, the AD536A measures the rms of the ac and dc levels present at the input, but shows an error for low frequency input as a function of the filter capacitor, C_{AV} , as shown in Figure 12. Thus, if a 4 μF capacitor is used, the additional average error at 10 Hz is 0.1%; at 3 Hz, the additional average error is 1%.

The accuracy at higher frequencies is according to specification. To reject the dc input, add a capacitor in series with the input, as shown in Figure 10. Note that the capacitor must be nonpolar. If the AD536A supply rails contain a considerable amount of high frequency ripple, it is advisable to bypass both supply pins to ground with 0.1 μF ceramic capacitors, located as close to the device as possible.

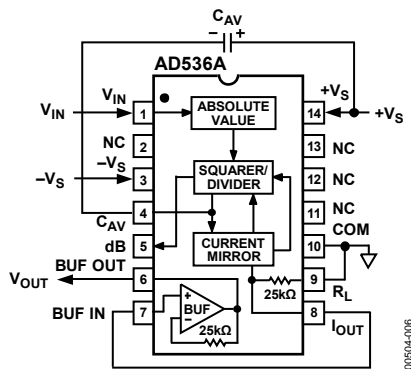

Figure 6. 14-Lead Standard RMS Connection

Figure 7. 10-Pin Standard RMS Connection

Figure 8. 20-Terminal Standard RMS Connection

The input and output signal ranges are a function of the supply voltages; these ranges are shown in Figure 21 and Figure 22. The AD536A can also be used in an unbuffered voltage output mode by disconnecting the input to the buffer. The output then appears unbuffered across the 25 k Ω resistor. The buffer amplifier can then be used for other purposes. Further, the AD536A can be used in a current output mode by disconnecting the 25 k Ω resistor from ground. The output current is available at Pin 8 (I_{OUT} , Pin 10 on the H-10 package) with a nominal scale of 40 μA per V rms input positive output.

OPTIONAL EXTERNAL TRIMS FOR HIGH ACCURACY

The accuracy and offset voltage of the AD536A is adjustable with external trims, as shown in Figure 9. R4 trims the offset. Note that the offset trim circuit adds 365 Ω in series with the internal 25 k Ω resistor. This causes a 1.5% increase in scale factor, which is compensated for by R1. The scale factor adjustment range is $\pm 1.5\%$.

The trimming procedure is as follows:

1. Ground the input signal, V_{IN} , and adjust R4 to provide 0 V output from Pin 6. Alternatively, adjust R4 to provide the correct output with the lowest expected value of V_{IN} .
2. Connect the desired full-scale input level to V_{IN} , either dc or a calibrated ac signal (1 kHz is the optimum frequency).
3. Trim R1 to provide the correct output at Pin 6. For example, 1.000 V dc input provides 1.000 V dc output. A ± 1.000 V peak-to-peak sine wave should provide a 0.707 V dc output. Any residual errors are caused by device nonlinearity.

The major advantage of external trimming is to optimize device performance for a reduced signal range; the AD536A is internally trimmed for a 7 V rms full-scale range.

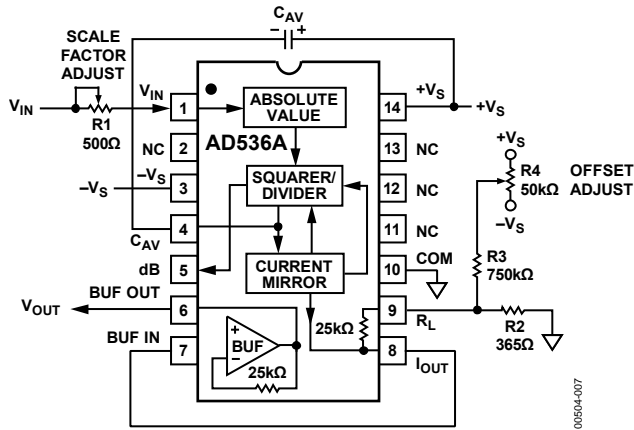

Figure 9. Optional External Gain and Output Offset Trims

SINGLE-SUPPLY OPERATION

Dual power supplies are shown in Figure 6, Figure 7, Figure 8, and Figure 9. The AD536A can also be powered by a single supply greater than 5 V, as shown in Figure 10. When using the AD536A with a single supply, the differential input stage must be biased above ground, and the input must be ac coupled. Biasing the device between the supply and ground is simply a matter of connecting Pin 10 (COM, Pin 2 on the H-10 package) to a resistor divider and bypassing the pin to ground. To minimize power consumption, the values of the resistors may be large, as Pin 10 current is only 5 μ A.

AC input coupling requires only Capacitor C2. A dc return is not necessary because it is provided internally. C2 is selected for the proper low frequency breakpoint with the input resistance of 16.7 k Ω ; for a cutoff at 10 Hz, C2 should be 1 μ F. The signal ranges in this connection are slightly more restricted than in the dual-supply connection. The input and output signal ranges are shown in Figure 21 and Figure 22. The load resistor, R_L, is necessary to provide output sink current.

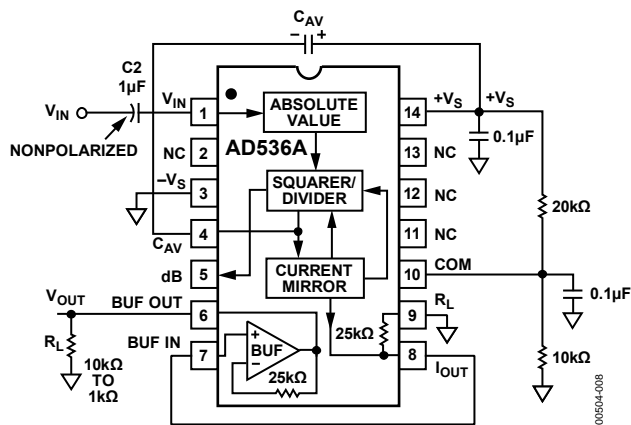

Figure 10. Single-Supply Connection

CHOOSING THE AVERAGING TIME CONSTANT

The AD536A computes the rms of both ac and dc signals. If the input is a slowly varying dc signal, the output of the AD536A tracks the input exactly.

At higher frequencies, the average output of the AD536A approaches the rms value of the input signal. The actual output of the AD536A differs from the ideal output by a dc (or average) error and some amount of ripple, as shown in Figure 11.

Figure 11. Typical Output Waveform for Sinusoidal Input

The dc error is dependent on the input signal frequency and the value of C_{AV}. Use Figure 12 to determine the minimum value of C_{AV}, which yields a given percentage of dc error above a given frequency using the standard rms connection.

The ac component of the output signal is the ripple. There are two ways to reduce the ripple. The first method involves using a large value of C_{AV}. Because the ripple is inversely proportional to C_{AV}, a tenfold increase in this capacitance affects a tenfold reduction in ripple.

When measuring waveforms with high crest factors, such as low duty cycle pulse trains, the averaging time constant should be at least 10 times the signal period. For example, a 100 Hz pulse rate requires a 100 ms time constant, which corresponds to a 4 μ F capacitor (time constant = 25 ms per μ F).

AD536A

The primary disadvantage in using a large C_{AV} to remove ripple is that the settling time for a step change in input level is increased proportionately. Figure 12 illustrates that the relationship between C_{AV} and 1% settling time is 115 ms for each microfarad of C_{AV} . The settling time is twice as great for decreasing signals as it is for increasing signals. The values in Figure 12 are for decreasing signals. Settling time also increases for low signal levels, as shown in Figure 13.

1PERCENT DC ERROR AND PERCENT RIPPLE (PEAK)
 Figure 12. Error/Settling Time Graph for Use with the Standard RMS Connection (See Figure 6 Through Figure 8)

Figure 13. Settling Time vs. Input Level

A better method to reduce output ripple is the use of a postfilter. Figure 14 shows a suggested circuit. If a single-pole filter is used (C_3 removed, R_x shorted) and C_2 is approximately twice the value of C_{AV} , the ripple is reduced, as shown in Figure 15, and settling time is increased. For example, with $C_{AV} = 1 \mu\text{F}$ and $C_2 = 2.2 \mu\text{F}$, the ripple for a 60 Hz input is reduced from 10% of reading to approximately 0.3% of reading.

The settling time, however, is increased by approximately a factor of 3. Therefore, the values of C_{AV} and C_2 can be reduced to permit faster settling times while still providing substantial ripple reduction.

The two-pole postfilter uses an active filter stage to provide even greater ripple reduction without substantially increasing the settling times over a circuit with a one-pole filter. The values of C_{AV} , C_2 , and C_3 can then be reduced to allow extremely fast settling times for a constant amount of ripple. Caution should be exercised in choosing the value of C_{AV} , because the dc error is dependent on this value and is independent of the postfilter.

For a more detailed explanation of these topics, refer to the *RMS to DC Conversion Application Guide*, 2nd Edition, available online from Analog Devices, Inc., at www.analog.com.

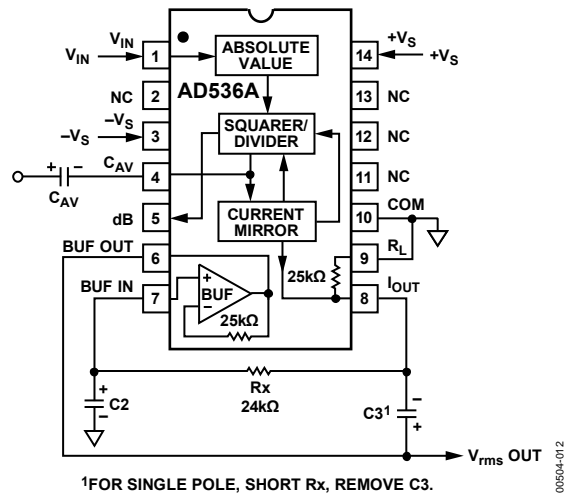

Figure 14. Two-Pole Postfilter

Figure 15. Performance Features of Various Filter Types (See Figure 6 to Figure 8 for Standard RMS Connection)

THEORY OF OPERATION

The AD536A embodies an implicit solution of the rms equation that overcomes the dynamic range as well as other limitations inherent in a straightforward computation of rms. The actual computation performed by the AD536A follows the equation

$$V_{rms} = \text{Avg} \left[\frac{V_{IN}^2}{V_{rms}} \right]$$

Figure 16 is a simplified schematic of the AD536A. Note that it is subdivided into four major sections: absolute value circuit (active rectifier), squarer/divider, current mirror, and buffer amplifier. The input voltage (V_{IN}), which can be ac or dc, is converted to a unipolar current (I_1) by the active rectifiers (A_1 , A_2). I_1 drives one input of the squarer/divider, which has the transfer function

$$I_4 = I_1^2 / I_3$$

The output current, I_4 , of the squarer/divider drives the current mirror through a low-pass filter formed by R_1 and the externally connected capacitor, C_{AV} . If the $R_1 C_{AV}$ time constant is much greater than the longest period of the input signal, then I_4 is effectively averaged. The current mirror returns a current I_3 , which equals $\text{Avg}[I_4]$, back to the squarer/divider to complete the implicit rms computation. Thus,

$$I_4 = \text{Avg}[I_1^2 / I_4] = I_1 \text{ rms}$$

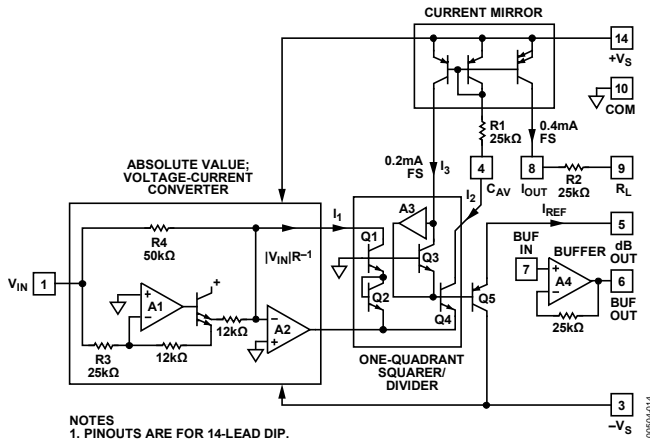

Figure 16. Simplified Schematic

The current mirror also produces the output current, I_{OUT} , which equals $2I_4$. I_{OUT} can be used directly or can be converted to a

voltage with R_2 and buffered by A_4 to provide a low impedance voltage output. The transfer function of the AD536A results in the following:

$$V_{OUT} = 2R_2 \times I_{rms} = V_{IN} \text{ rms}$$

The dB output is derived from the emitter of Q_3 because the voltage at this point is proportional to $-\log V_{IN}$. The emitter follower, Q_5 , buffers and level shifts this voltage so that the dB output voltage is zero when the externally supplied emitter current (I_{REF}) to Q_5 approximates I_3 .

CONNECTIONS FOR dB OPERATION

The logarithmic (or decibel) output of the AD536A is one of its most powerful features. The internal circuit computing dB works accurately over a 60 dB range. The connections for dB measurements are shown in Figure 17.

Select the 0 dB level by adjusting R_1 for the proper 0 dB reference current (which is set to cancel the log output current from the squarer/divider at the desired 0 dB point). The external op amp provides a more convenient scale and allows compensation of the $+0.33\%/^{\circ}\text{C}$ scale factor drift of the dB output pin.

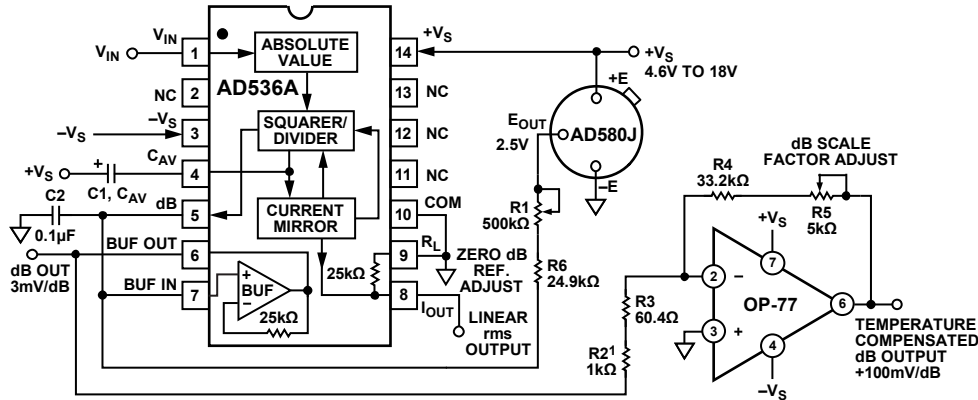

The temperature-compensating resistor, R_2 , is available online in several styles from Precision Resistor Company, Inc., (Part Number AT35 and Part Number ST35). The average temperature coefficients of R_2 and R_3 result in the $+3300$ ppm required to compensate for the dB output. The linear rms output is available at Pin 8 on the DIP or Pin 10 on the header device with an output impedance of $25 \text{ k}\Omega$. Some applications require an additional buffer amplifier if this output is desired.

For dB calibration,

1. Set $V_{IN} = 1.00 \text{ V dc}$ or 1.00 V rms .
2. Adjust R_1 for dB output = 0.00 V .
3. Set $V_{IN} = +0.1 \text{ V dc}$ or 0.10 V rms .
4. Adjust R_5 for dB output = -2.00 V .

Any other desired 0 dB reference level can be used by setting V_{IN} and adjusting R_1 accordingly. Note that adjusting R_5 for the proper gain automatically provides the correct temperature compensation.

Figure 17. dB Connection

FREQUENCY RESPONSE

The AD536A utilizes a logarithmic circuit in performing the implicit rms computation. As with any log circuit, bandwidth is proportional to signal level. The solid lines in the graph of Figure 18 represent the frequency response of the AD536A at input levels from 10 mV rms to 7 V rms. The dashed lines indicate the upper frequency limits for 1%, 10%, and ± 3 dB of reading additional error. For example, note that a 1 V rms signal produces less than 1% of reading additional error up to 120 kHz. A 10 mV rms signal can be measured with 1% of reading additional error (100 μ V) up to only 5 kHz.

Figure 18. High Frequency Response

AC MEASUREMENT ACCURACY AND CREST FACTOR

Crest factor is often overlooked when determining the accuracy of an ac measurement. The definition of crest factor is the ratio of the peak signal amplitude to the rms value of the signal ($CF = V_p/V_{rms}$). Most common waveforms, such as sine and triangle waves, have relatively low crest factors (<2). Waveforms that resemble low duty cycle pulse trains, such as those occurring in switching power supplies and SCR circuits, have high crest factors. For example, a rectangular pulse train with a 1% duty cycle has a crest factor of 10 ($CF = 1/\eta$).

Figure 19 illustrates a curve of reading error for the AD536A for a 1 V rms input signal with crest factors from 1 to 11. A rectangular pulse train (pulse width = 100 μ s) was used for this test because it is the worst-case waveform for rms measurement (all of the energy is contained in the peaks). The duty cycle and peak amplitude were varied to produce crest factors from 1 to 11 while maintaining a constant 1 V rms input amplitude.

ORDERING GUIDE

| Model | Temperature Range | Package Description | Package Option |
|------------------------|-------------------|--|----------------|
| AD536AJD | 0°C to +70°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536AJDZ ¹ | 0°C to +70°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536AKD | 0°C to +70°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536AKDZ ¹ | 0°C to +70°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536AJH | 0°C to +70°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536AJHZ ¹ | 0°C to +70°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536AKH | 0°C to +70°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536AKHZ ¹ | 0°C to +70°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536AJQ | 0°C to +70°C | 14-Lead Ceramic Dual In-Line Package [CERDIP] | Q-14 |
| AD536AKQ | 0°C to +70°C | 14-Lead Ceramic Dual In-Line Package [CERDIP] | Q-14 |
| AD536ASD | -55°C to +125°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536ASD/883B | -55°C to +125°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| AD536ASE/883B | -55°C to +125°C | 20-Terminal Ceramic Leadless Chip Carrier [LCC] | E-20 |
| AD536ASH | -55°C to +125°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536ASH/883B | -55°C to +125°C | 10-Pin Metal Header Package [TO-100] | H-10 |
| AD536ASCHIPS | -55°C to +125°C | Die | |
| 5962-89805012A | -55°C to +125°C | 20-Terminal Ceramic Leadless Chip Carrier [LCC] | E-20 |
| 5962-8980501CA | -55°C to +125°C | 14-Lead Side-Brazed Ceramic Dual In-Line Package [SBDIP] | D-14 |
| 5962-8980501IA | -55°C to +125°C | 10-Pin Metal Header Package [TO-100] | H-10 |
