Monolithic Peak Detector with Reset-and-Hold Mode

## FEATURES

Monolithic Design for Reliability and Low Cost
High Slew Rate: $0.5 \mathrm{~V} / \mu \mathrm{s}$
Low Droop Rate
$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}: 0.1 \mathrm{mV} / \mathrm{ms}$
$\mathrm{T}_{\mathrm{A}}=125^{\circ} \mathrm{C}: 10 \mathrm{mV} / \mathrm{ms}$
Low Zero-Scale Error: $\mathbf{4 m V}$
Digitally Selected Hold and Reset Modes
Reset to Positive or Negative Voltage Levels
Logic Signals TTL and CMOS Compatible
Uncommitted Comparator On-Chip
Available in Die Form

## GENERAL DESCRIPTION

The PKD01 tracks an analog input signal until a maximum amplitude is reached. The maximum value is then retained as a peak voltage on a hold capacitor. Being a monolithic circuit, the PKD01 offers significant performance and package density advantages over hybrid modules and discrete designs without sacrificing system versatility. The matching characteristics attained in a monolithic circuit provide inherent advantages when charge injection and droop rate error reduction are primary goals.
Innovative design techniques maximize the advantages of monolithic technology. Transconductance ( $\mathrm{g}_{\mathrm{m}}$ ) amplifiers were chosen over conventional voltage amplifier circuit building blocks. The $\mathrm{g}_{\mathrm{m}}$ amplifiers simplify internal frequency compensation, minimize acquisition time and maximize circuit accuracy. Their outputs are easily switched by low glitch current steering circuits. The steered outputs are clamped to reduce charge injection errors upon entering the hold mode or exiting the reset mode. The inherently low zero-scale error is further reduced by active Zener-Zap trimming to optimize overall accuracy.

REV. A
Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices.

## FUNCTIONAL BLOCK DIAGRAM

SWITCHES SHOWN FOR: RST $=" 0, " \frac{}{\text { DET }}=" 0 "$

The output buffer amplifier features an FET input stage to reduce droop rate error during lengthy peak hold periods. A bias current cancellation circuit minimizes droop error at high ambient temperatures.
Through the $\overline{\mathrm{DET}}$ control pin, new peaks may either be detected or ignored. Detected peaks are presented as positive output levels. Positive or negative peaks may be detected without additional active circuits, since Amplifier A can operate as an inverting or noninverting gain stage.
An uncommitted comparator provides many application options. Status indication and logic shaping/shifting are typical examples.

## NOTES

${ }^{1}$ Guaranteed by design.
${ }^{2} \overline{\mathrm{DET}}=1, \mathrm{RST}=0$.
${ }^{3}$ Due to limited production test times, the droop current corresponds to junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$. The droop current vs. time (after power-on) curve clarified this point. Since most devices (in use) are on for more than 1 second, ADI specifies droop rate for ambient temperature ( $\mathrm{T}_{\mathrm{A}}$ ) also. The warmed-up ( $\mathrm{T}_{\mathrm{A}}$ ) droop current specification is correlated to the junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$ value. ADI has a droop current cancellation circuit that minimizes droop current at high temperature. Ambient $\left(\mathrm{T}_{\mathrm{A}}\right)$ temperature specifications are not subject to production testing.
Specifications subject to change without notice.

NOTES
${ }^{1}$ Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
${ }^{2}$ Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL CHARACTERISTICS

| Package Type | $\boldsymbol{\theta}_{\mathbf{J A}}{ }^{\boldsymbol{*}}$ | $\boldsymbol{\theta}_{\mathbf{J C}}$ | Unit |

NOTES
${ }^{1}$ Burn-in is available on commercial and industrial temperature range parts in cerdip, plastic DIP, and TO-can packages.
${ }^{2}$ For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

## PIN CONFIGURATION

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the PKD01 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## NOTES

${ }^{1}$ Guaranteed by design.
${ }^{2} \overline{\mathrm{DET}}=1, \mathrm{RST}=0$.
${ }^{3}$ Due to limited production test times, the droop current corresponds to junction temperature ( $\mathrm{T}_{\mathrm{J}}$ ). The droop current vs. time (after power-on) curve clarifies this point. Since most devices (in use) are on for more than 1 second, ADI specifies droop rate for ambient temperature ( $\mathrm{T}_{\mathrm{A}}$ ) also. The warmed-up ( $\mathrm{T}_{\mathrm{A}}$ ) droop current specification is correlated to the junction temperature $\left(T_{J}\right)$ value. ADI has a droop current cancellation circuit that minimizes droop current at high temperature. Ambient $\left(\mathrm{T}_{\mathrm{A}}\right)$ temperature specifications are not subject to production testing.

## THEORY OF OPERATION

The typical peak detector uses voltage amplifiers and a diode or an emitter follower to charge the hold capacitor, $\mathrm{C}_{\mathrm{H}}$, indirectionally (see Figure 1). The output impedance of A plus $\mathrm{D}_{1}$ 's dynamic impedance, $r_{d}$, make up the resistance which determines the feedback loop pole. The dynamic impedance is $r_{d}=\frac{k T}{q I_{d}}$, where $I_{d}$ is the capacitor charging current.

The pole moves toward the origin of the $S$ plane as $I_{d}$ goes to zero. The pole movement in itself will not significantly lengthen the acquisition time since the pole is enclosed in the system feedback loop.

Figure 1. Conventional Voltage Amplifier Peak Detector
When the moving pole is considered with the typical frequency compensation of voltage amplifiers however, there is a loop stability problem. The necessary compensation can increase the required acquisition time. ADI's approach replaces the input voltage amplifier with a transconductance amplifier (see Figure 2).
The PKD01 transfer function can be reduced to:

$$
\frac{V_{O U T}}{V_{I N}}=\frac{1}{1+\frac{s C_{H}}{g_{m}}+\frac{1}{g_{m} R_{O U T}}} \approx \frac{1}{1+\frac{s C_{H}}{g_{m}}}
$$

where: $g_{m} \approx 1 \mu \mathrm{~A} / \mathrm{mV}, R_{\text {OUT }} \approx 20 \mathrm{M} \Omega$.
The diode in series with A's output (see Figure 2) has no effect because it is a resistance in series with a current source. In addition to simplifying the system compensation, the input transconductance amplifier output current is switched by current steering. The steered output is clamped to reduce and match any charge injection.

Figure 2. Transconductance Amplifier Peak Detector
Figure 3 shows a simplified schematic of the reset $\mathrm{g}_{\mathrm{m}}$ amplifier, B. In the track mode, $Q_{1}$ and $Q_{4}$ are $O N$ and $Q_{2}$ and $Q_{3}$ are OFF. A current of $2 I$ passes through $D_{1}, I$ is summed at $B$ and passes through $Q_{1}$, and is summed with $g_{m} V_{I N}$. The current sink can absorb only 3 I , thus the current passing through $\mathrm{D}_{2}$ can
only be: $2 \mathrm{~K}-g_{\mathrm{m}} \mathrm{V}_{\text {IN }}$. The net current into the hold capacitor node then, is $\mathrm{g}_{\mathrm{m}} \mathrm{V}_{\mathrm{IN}}\left[\mathrm{I}_{\mathrm{H}}=2 \mathrm{I}-\left(2 \mathrm{I}-\mathrm{g}_{\mathrm{m}} \mathrm{V}_{\mathrm{IN}}\right)\right]$. In the hold mode, $\mathrm{Q}_{2}$ and $\mathrm{Q}_{3}$ are ON while $\mathrm{Q}_{1}$ and $\mathrm{Q}_{4}$ are OFF. The net current into the top of $D_{1}$ is $-I$ until $D_{3}$ turns ON. With $Q_{1} O F F$, the bottom of $D_{2}$ is pulled up with a current $I$ until $D_{4}$ turns $O N$, thus, $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ are reverse biased by $<0.6 \mathrm{~V}$, and charge injection is independent of input level.
The monolithic layout results in points $A$ and $B$ having equal nodal capacitance. In addition, matched diodes $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ have equal diffusion capacitance. When the transconductance amplifier outputs are switched open, points $A$ and $B$ are ramped equally, but in opposite phase. Diode clamps $D_{3}$ and $D_{4}$ cause the swings to have equal amplitudes. The net charge injection (voltage change) at node C is therefore zero.

Figure 3. Transconductance Amplifier with Low Glitch Current Switch
The peak transconductance amplifier, A is shown in Figure 4. Unidirectional hold capacitor charging requires diode $D_{1}$ to be connected in series with the output. Upon entering the peak hold mode $D_{1}$ is reverse-biased. The voltage clamp limits charge injection to approximately 1 pC and the hold step to 0.6 mV .
Minimizing acquisition time dictates a small $\mathrm{C}_{\mathrm{H}}$ capacitance. A 1000 pF value was selected. Droop rate was also minimized by providing the output buffer with an FET input stage. A current cancellation circuit further reduces droop current and minimizes the gate current's tendency to double for every $10^{\circ}$ temperature change.

## PKDO1

## APPLICATIONS INFORMATION

## Optional Offset Voltage Adjustment

Offset voltage is the primary zero scale error component since a variable voltage clamp limits voltage excursions at $\mathrm{D}_{1}$ 's anode and reduces charge injection. The PKD01 circuit gain and operational mode (positive or negative peak detection) determine the applicable null circuit. Figures 5 through 8 are suggested circuits. Each circuit also corrects amplifier C offset voltage error.

Figure 5. Vos Null Circuit for Unity Gain Positive Peak Detector

2. DISCONNECT $R_{C}$ FROM $C_{H}$ AFTER AMPLIFIER A ADJUSTMENT.
3. REPEAT NULL CIRCUIT FOR RESET BUFFER AMPLIFIER B IF REQUIRED.

Figure 6. Vos Null Circuit for Differential Peak Detector
A. Nulling Gated Output $\boldsymbol{g}_{\boldsymbol{m}}$ Amplifier A. Diode $\mathrm{D}_{1}$ must be conducting to close the feedback circuit during amplifier A $\mathrm{V}_{\mathrm{OS}}$ adjustment. Resistor network $\mathrm{R}_{\mathrm{A}}-\mathrm{R}_{\mathrm{C}}$ cause $\mathrm{D}_{1}$ to conduct slightly. With DET $=0$ and $\mathrm{V}_{\text {IN }}=0 \mathrm{~V}$, monitor the PKD01 output. Adjust the null potentiometer until $\mathrm{V}_{\mathrm{OUT}}=0 \mathrm{~V}$. After adjustment, disconnect $\mathrm{R}_{\mathrm{C}}$ from $\mathrm{C}_{\mathrm{H}}$.
B. Nulling Gated $\boldsymbol{g}_{m}$ Amplifier B. Set Amplifier B signal input to $\mathrm{V}_{\mathrm{IN}}=0 \mathrm{~V}$ and monitor the PKD01 output. Set DET = $1, \mathrm{RST}=1$ and adjust the null potentiometer for $\mathrm{V}_{\text {OUT }}=0 \mathrm{~V}$. The circuit gain-inverting or noninverting-will determine which null circuit illustrated in Figures 5 through 8 is applicable.

Figure 7. Vos Null Circuit for Negative Peak Detector

Figure 8. Vos Null Circuit for Positive Peak Detector with Gain

## PEAK HOLD CAPACITOR RECOMMENDATIONS

The hold capacitor $\left(\mathrm{C}_{\mathrm{H}}\right)$ serves as the peak memory element and compensating capacitor. Stable operation requires a minimum value of 1000 pF . Larger capacitors may be used to lower droop rate errors, but acquisition time will increase.
Zero scale error is internally trimmed for $\mathrm{C}_{\mathrm{H}}=1000 \mathrm{pF}$. Other $\mathrm{C}_{\mathrm{H}}$ values will cause a zero scale shift which can be approximated with the following equation.

$$
\Delta V_{Z S}(m V)=\frac{1 \times 10^{3}(p C)}{C_{H}(n F)}-0.6 m V
$$

The peak hold capacitor should have very high insulation resistance and low dielectric absorption. For temperatures below $85^{\circ} \mathrm{C}$, a polystyrene capacitor is recommended, while a Teflon capacitor is recommended for high temperature environments.

## CAPACITOR GUARDING AND GROUND LAYOUT

Ground planes are recommended to minimize ground path resistance. Separate analog and digital grounds should be used. The two ground systems are tied together only at the common system ground. This avoids digital currents returning to the system ground through the analog ground path.

Figure 9. $C_{H}$ Terminal (Pin 4) Guarding. See Text. The $\mathrm{C}_{\mathrm{H}}$ terminal (Pin 4) is a high impedance point. To minimize gain errors and maintain the PKD01's inherently low droop rate, guarding Pin 4 as shown in Figure 9 is recommended.

## COMPARATOR

The comparator output high level $\left(\mathrm{V}_{\mathrm{OH}}\right)$ is set by external resistors. It is possible to optimize noise immunity while interfacing to all standard logic families-TTL, DTL, and CMOS. Figure 10 shows the comparator output with external level-setting resistors. Table I gives typical R1 and R2 values for common circuit conditions.
The maximum comparator high output voltage $\left(\mathrm{V}_{\mathrm{OH}}\right)$ should be limited to:

$$
V_{O H}(\text { maximum })<V+-2.0 V
$$

With the comparator in the low state $\left(\mathrm{V}_{\mathrm{OL}}\right)$, the output stage will be required to sink a current approximately equal to $\mathrm{V}_{\mathrm{C}} / \mathrm{R} 1$.

Figure 10. Comparator Output with External Level-Setting Resistors

Table I.

| $\mathbf{V}_{\mathbf{C}}$ | $\mathbf{V}_{\mathbf{O H}}$ | $\mathbf{R 1}$ | $\mathbf{R 2}$ |

| 15 | 7.5 | $7.5 \mathrm{k} \Omega$ | $7.5 \mathrm{k} \Omega$ |
| 15 | 10.0 | $7.5 \mathrm{k} \Omega$ | $15 \mathrm{k} \Omega$ |

$$
R 1 \approx \frac{V_{C}}{I_{S I N K}}
$$

$$
R 2 \approx\left(\frac{1}{\frac{V_{C}}{V_{O H}}-1}\right)
$$

PEAK DETECTOR LOGIC CONTROL (RST, $\overline{\text { DET }}$ )
The transconductance amplifier outputs are controlled by the digital logic signals RST and $\overline{\mathrm{DET}}$. The PKD01 operational mode is selected by steering the current $\left(\mathrm{I}_{1}\right)$ through $\mathrm{Q}_{1}$ and $\mathrm{Q}_{2}$, thus providing high-speed switching and a predictable logic threshold. The logic threshold voltage is 1.4 V when digital ground is at zero volts.
Other threshold voltages ( $\mathrm{V}_{\mathrm{TH}}$ ) may be selected by applying the formula:

$$
V_{T H} \approx 1.4 V+\text { Digital Ground Potential. }
$$

For proper operation, digital ground must always be at least 3.5 V below the positive supply and 2.5 V above the negative supply. The RST or $\overline{\mathrm{DET}}$ signal must always be at least 2.8 V above the negative supply.
Operating the digital ground at other than zero volts does influence the comparator output low voltage. The $\mathrm{V}_{\mathrm{OL}}$ level is referenced to digital ground and will follow any changes in digital ground potential:

$$
V_{O L} \approx 0.2 V+\text { Digital Ground Potential. }
$$
