MAXIM

Fault-Protected, Single 8-to-1/ Dual 4-to-1 Multiplexers

General Description

The MAX4708/MAX4709 8-to-1 and dual 4-to-1 fault-protected multiplexers are pin compatible with the industry-standard DG508/DG509. The MAX4708/MAX4709 are similar to the MAX4508/MAX4509, but these devices do not have clamp diodes to the supply rails on the switch outputs. These multiplexers feature fault-protected inputs, Rail-to-Rail® signal-handling capability, and do not require power-supply sequencing.

Both devices offer ±40V overvoltage protection with the supplies off, ±36V protection with the supplies on, and feature 400Ω (max) on-resistance with 15Ω (max) matching between channels. The MAX4708/MAX4709 operate with dual supplies of ±4.5V to ±20V or a single supply of +9V to +36V. All digital inputs have TTL logic-compatible thresholds, ensuring both TTL and CMOS logic compatibility when using a single +12V supply or dual ±15V supplies.

For low-voltage applications requiring fault protection, refer to the MAX4711/MAX4712/MAX4713 data sheet.

Applications

Data-Acquisition Systems

Industrial and Process Control

Avionics

Signal Routing

Redundancy/Backup Systems

ATE Systems

Hot Swap

Features

- **No Power-Supply Sequencing Required**
- **All Channels Off with Power Off**
- **Rail-to-Rail Signal Handling**
- **400Ω (max) On-Resistance**
- **±40V Fault Protection with Power Off**
- **±25V Fault Protection with ±15V Supplies**
- **100ns Fault-Response Time**
- **±4.5V to ±20V Dual Supplies**
- **+9V to +36V Single Supply**
- **TTL/CMOS-Compatible Logic Inputs**

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX4708ESE	-40°C to +85°C	16 Narrow SO
MAX4708EWE	-40°C to +85°C	16 Wide SO
MAX4708EPE	-40°C to +85°C	16 Plastic DIP
MAX4709ESE	-40°C to +85°C	16 Narrow SO
MAX4709EWE	-40°C to +85°C	16 Wide SO
MAX4709EPE	-40°C to +85°C	16 Plastic DIP

16 Narrow SO (derate 8.70mW/°C above +70°C) 696mW
16 Plastic DIP (derate 10.53mW/°C above +70°C) 842mW
16 Wide SO (derate 9.52mW/°C above +70°C).....762mW
Operating Temperature Range
MAX4708E_ E/MAX4709E_E .....-40°C to +85°C
Junction Temperature..... +150°C
Storage Temperature Range .....-65°C to +160°C
Lead Temperature (soldering, 10s) .....+300°C

Note 1: COM_, EN, and A_ pins are not fault protected. Signals on COM_, EN, or A_ exceeding V+ or V- are clamped by internal diodes. Limit forward-diode current to maximum current rating.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS—Dual Supplies

Note 2: The algebraic convention is used in this data sheet; the most negative value is shown in the minimum column.
Note 3: NO_ pins are fault protected and COM_ pins are not fault protected. The max input voltage on NO_ pins depends on the COM_ load configuration. Generally, the max input voltage is ±36V with ±15V supplies and a load referred to ground. For more detailed information, see the *NO_ Input Voltage* section.
Note 4: Guaranteed by design and not production tested.
Note 5: $\Delta R_{ON} = R_{ON(MAX)} - R_{ON(MIN)}$.
Note 6: Leakage parameters are 100% tested at the maximum rated hot temperature and guaranteed by correlation at T_A = +25°C.
Note 7: Dynamic testing is 100% functionally tested on the ATE system and correlated with the initial design characterization per Figures 2 and 3.
Note 8: Off-Isolation = $20 \times \log_{10} (V_{COM\_} / V_{NO\_})$, where $V_{COM\_}$ = output and $V_{NO\_}$ = input to open switch.
Note 9: Between any two analog inputs.
Note 10: Guaranteed by testing with dual supplies.

Fault-Protected, Single 8-to-1/ Dual 4-to-1 Multiplexers

Detailed Description

Several unique features differentiate the MAX4708/MAX4709 from traditional fault-protected multiplexers. First, instead of the three series FETs utilized in older designs, the MAX4708/MAX4709 design employs two parallel FETs for lower on-resistance and improved flatness. Second, older devices limited the range of signal amplitudes the switch could pass by as much as 3V below the supply rails. The MAX4708/MAX4709 feature rail-to-rail signal handling that allows the devices to transmit signals with amplitudes at or slightly beyond the supply rails. Finally, in former designs (MAX4508/MAX4509), when a fault occurred, the devices clamped and held the output voltage at the appropriate supply rail until the fault was removed. Instead, the MAX4708/MAX4709 now disconnect COM_ from NO_ during a fault condition, making COM_ a high-impedance output as long as the fault is present. Operation is identical for both positive and negative fault polarities.

When the NO_ voltage ranges beyond supply rails (fault condition), the NO_ input becomes high impedance, regardless of the switch state or load resistance. If power is removed, and the fault voltage is still present, the NO_ terminals remain high impedance. The fault voltage can be up to ±40V, with V+ = V- = 0.

The COM_ pins are not fault protected. Limit any voltage sources connected to COM_ to the supply rails.

Figure 1 shows the internal construction of a single normally open (NO) switch, with the analog signal paths shown in bold. The parallel combination of N-channel FET N1 and P-channel FET P1 form the analog switch. During normal operation, these FETs are driven on and off simultaneously according to the control voltages on A_. During a fault condition, both FETs turn off.

NO_ Input Voltage

The maximum allowable input voltage for safe operation depends on whether supplies are on or off, and the load configuration on COM_. If COM_ is referred to a voltage other than ground, but within the supplies, $V_{NO\_}$ can range higher or lower than the supplies, provided the absolute value of $|V_{NO\_} - V_{COM\_}|$ is less than 40V.

For example, with V+ = V- = 0, if the load is referred to +10V at COM_, then the NO_ voltage range can be from +50V to -30V. If the supplies are ±15V and COM_ is referenced to ground through a load, the maximum NO_ voltage is ±36V. If the supplies are off and the COM output is referenced to ground, the maximum NO_ voltage is ±40V.

Normal Operation

Two comparators continuously compare the voltage on NO_ with V+ and V- supply voltages. When the signal on NO_ ranges between V+ and V-, the multiplexer operates normally, with FETs N1 and P1 turning on and off in response to the control signals on A_ (Figure 1). When the switch state is on, the parallel combination of N1 and P1 forms a low-value resistor between NO_ and COM_ so that signals pass equally well in either direction. When the switch state is off, both NO_ and COM_ are high-impedance inputs.

Fault Conditions

A fault condition occurs when the voltage at any NO_ input exceeds the supply rail. At this point, the output of one of the two fault comparators goes high, effectively turning OFF both FETs N1 and P1. With the two FETs in the OFF position, both the switch input (NO_) and the output (COM_) go into a high-impedance state. They remain high impedance regardless of the state of the control voltages in A_ and EN, until the fault is removed. The input voltage must not exceed the absolute maximum rating at any moment (see the *Absolute Maximum Ratings* section).

Transient Fault Condition

When a fast rising or falling transient on NO_ exceeds V+ or V-, there is a 100ns delay before the fault protection turns on (see the *Typical Operating Characteristics*, Fault Response Time). COM_ follows NO_ until the fault protection turns on. This delay is due to the switch on-resistance and circuit capacitance to ground. When the input transient returns to within the supply rails, there is a longer output recovery time (see the *Typical Operating Characteristics*, Fault Response Times). These values depend on the COM_ output resistance and capacitance. Higher COM_ output resistance and capacitance increase the recovery times. The delays do not depend on the fault amplitude.

COM and A_

The GND, COM_, and A_ pins are not fault protected. ESD-protection diodes internally connect A_ to both V+ and V-. If a signal on GND, COM_, or A_ exceeds V+ or V- by more than 300mV, excessive current can flow to or from the supplies, possibly damaging the device.

Logic-Level Thresholds

The logic-level thresholds are CMOS and TTL compatible with V+ = +15V and V- = -15V. Logic levels change as V+ increases (see the *Typical Operating Characteristics*, Logic-Level Threshold Voltage vs. Supply Voltage.)

Applications Information

Ground

V+ and GND power the internal logic and logic-level translators. The logic-level translators convert the logic-level inputs to V+ and V- to drive the gates of the internal FETs. In this design, there is no galvanic connection inside the MAX4708/MAX4709 between the analog signal paths and GND. ESD-protection diodes connect A_ to V+ and V-.

Supply Current Reduction

Driving the logic signals rail-to-rail from 0 to +15V or -15V to +15V reduces the current consumption from 370µA (typ) to 200µA (typ) (see the *Electrical Characteristic*s table, Power Supplies).

Power Supplies

The MAX4708/MAX4709 operate with bipolar supplies between ±4.5V and ±20V. The V+ and V- supplies need not be symmetrical, but V+ - V- cannot exceed the 44V absolute maximum rating.

The MAX4708/MAX4709 operate from single supplies between +9V and +36V when V- is connected to GND.

Chip Information

TRANSISTOR COUNT: 527

SUBSTRATE INTERNALLY CONNECTED TO V+

Package Information

For the latest package outline information, go to **www.maxim-ic.com/packages**.
