

# NCP590

## Dual Output, High Accuracy, Ultra Low Dropout CMOS LDO

The NCP590 is a family of very high precision dual-output CMOS LDOs offered in a 2x2 DFN8 package. Each output is capable of delivering up to 300 mA and is available in voltages from 0.8 V to 5 V.

The set point output voltage is accurate to within  $\pm 0.9\%$  with an operating voltage input up to 5.5 V. With its ultra low dropout characteristics and low quiescent and ground current consumption, the NCP590 is ideal for all battery operated consumer and microprocessor applications. The NCP590 is protected against short circuit and thermal overload conditions.

### Features

- Dual Outputs, Each Supporting up to 300 mA Current
- Available in Output Combinations Ranging from 0.8 V to 5.0 V
- 2.1 V to 5.5 V  $V_{CC}$  Operating Supply Range
- Ultra-High Accuracy (0.9% max at 100 mA load & 25°C)
- Each Output has a Dedicated Enable Control Pin
- Enable Threshold Supports sub-1 V Systems
- Very Low Drop Out Voltage (50 mV typ @ 100 mA load)
- Low Noise ( $\sim 20 \mu V_{rms}$ ) without Bypass Capacitor
- Ultra Low Shutdown Current (0.2  $\mu A$ )
- Low Quiescent and Ground Current (80 - 100  $\mu A$  typ.)
- Thermal Shutdown and Current Limit Protection
- Active Output Discharge when Disabled
- No Minimum Output Current Required for Stability
- Requires  $C_{out}$  of only 1.0  $\mu F$  (any ESR) for Stability
- Stable with Any Type of Capacitor (including MLCC) and Zero Load
- Input Under Voltage Lock Out (UVLO)
- Internally Compensated Regulator for Quick Transient Response
- Space-Efficient 2x2 DFN8 Package
- This is a Pb-Free Device

### Applications

- Cellular Phones
- Cameras
- MP3/CD Players, PDA's, Camcorders
- DSP Supplies
- Portable Info-tronics
- PCMCIA Cards
- Networking Systems, DSL/Cable Modems

Figure 1. Typical Application

## PIN FUNCTION

Pin No.	Symbol	Function
1	$V_{in}$	Input; Bypass directly at the IC with a 1 $\mu$ F ceramic capacitor to Ground
2	EN1	Enable for output regulator 1; raise above 0.95 V to enable $V_{out1}$
3	EN2	Enable for output regulator 2; raise above 0.95 V to enable $V_{out2}$
4, 5	NC	NC; Do not make connection to these pins
6	GND	Ground
PAD	GND	The thermal pad should be connected to ground for best thermal performance. Float if necessary
7	$V_{out2}$	Output 2; Bypass to GND with a capacitor, $4.7 \mu\text{F} \geq C \geq 0.7 \mu\text{F}$ , any ESR
8	$V_{out1}$	Output 1; Bypass to GND with a capacitor, $4.7 \mu\text{F} \geq C \geq 0.7 \mu\text{F}$ , any ESR

## ABSOLUTE MAXIMUM RATINGS $T_J = -40^{\circ}\text{C}$ to $125^{\circ}\text{C}$

Pin Symbol, Parameter		Symbol	Condition	Min	Max	Unit
$V_{IN}$ , Input to regulator	Voltage	$V_{IN}$		-0.3	6.0	V
	Current	$I_{IN}$		-	Internally Limited	
$V_{IN}$ , Input peak Transient Voltage to regulator wrt GND		$V_{IN}$			7.0	V
$V_{OUT1}$ , $V_{OUT2}$ , Regulated Output	Voltage	$V_{OUT}$		-0.3	$V_{IN} + 0.3$ or 6.0 (Note 1)	V
	Current	$I_{OUT}$		-	Internally Limited	
EN1, EN2, Enable Input		$V_{EN}$		-0.3	$V_{IN} + 0.3$ or 6.0 (Note 1)	V
Junction Temperature		$T_J$		-	125	$^{\circ}\text{C}$
Storage Temperature		$T_{stg}$		-50	150	
ESD Capability, Human body model (Note 3)		$ESD_{HB}$		-2	2	kV
ESD Capability, Machine model (Note 3)		$ESD_{MM}$		-200	200	V
$V_{outx} - V_{in}$ (Note 2)		$V_{RB}$		-	0.3	V

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

1. Which ever limit is lower
2. Exceeding this value will turn on the body diode of the PMOS driver (reference Figure 2).

## THERMAL RESISTANCE

Parameter		Symbol	Condition	Value	Unit
Junction-to-Ambient	2X2 DFN 1 oz Cu	$\theta_{JA}$	207.0 sq mm 1 oz Cu	158	$^{\circ}\text{C}/\text{W}$

## APPLICATION INFORMATION

**Output Regulator**

The output is controlled by a precision trimmed reference and error amplifier. The output has saturation control for regulation while the input voltage is low, preventing over saturation. Current limit and voltage monitors complement the regulator design to give safe operating signals to the processor and control circuits.

Standard linear regulator design circuitry consists of only an active output driver providing current at the regulated voltage with resistors from the regulated output to ground (used in the feedback loop). This provides good turn-on characteristics from the active PFET output driver, but turn-off characteristics are determined by the output capacitor values and impedance of the load in parallel with the internal resistors in the feedback loop. The turn-off time in the situation with high impedance loads will be slow. The NCP590 has active pull-down transistors which turn on during device turn-off creating efficient fast turn-offs independent of loading.

**Stability Considerations**

The input capacitor  $C_{in}$  in Figure 3 is necessary to provide low impedance to the input of the regulator.

The output or compensation capacitor  $C_{outx}$  helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures ( $-25^{\circ}\text{C}$  to  $-40^{\circ}\text{C}$ ), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information.

Stability is guaranteed at values  $C_{OUT} = 0.7 \mu\text{F}$  to  $4.7 \mu\text{F}$  and any ESR within the operating temperature range.

**Calculating Power Dissipation in a Dual Output Linear Regulator**

The maximum power dissipation for a dual output regulator (Figure x) is:

$$P_D = (V_{IN} - V_{OUT1}) \times I_{OUT1} + (V_{IN} - V_{OUT2}) \times I_{OUT2} + V_{IN} \times I_{GND} \quad (1)$$

where:

$V_{IN}$  is the maximum input voltage,

$V_{OUT}$  is the output voltage for each output,

$I_{OUT}$  is the output current for each output in the application, and

$I_{GND}$  is the quiescent or ground current the regulator consumes at  $I_{OUT}$ .

Once the value of  $P_{D(max)}$  is known, the maximum permissible value of  $R_{\theta JA}$  can be calculated:

$$R_{\theta JA} = (125^{\circ}\text{C} - T_A) / P_D \quad (\text{eq. 1})$$

The value of  $R_{\theta JA}$  can then be compared with those in the thermal resistance section of the data sheet. Those board areas with  $R_{\theta JA}$ 's less than the calculated value in equation 2 will keep the die temperature below  $125^{\circ}\text{C}$ . In some cases, none of the circuit board areas will be sufficient to dissipate the heat generated by the IC, and an external heat sink will be required. The current flow and voltages are shown in the Measurement Circuit Diagram. A chart showing thermal resistance vs. pcb heat spreader area is shown below.

**Enable**

Enabling the two outputs is controlled by two independent pins, EN1 and EN2. A high (above the high input threshold) on these logic level input pins causes the outputs to turn on.

Normal operation allows for input voltages to these pins to 0.3 V above  $V_{IN}$ . It is sometimes necessary to interface logic outputs from different operating voltages into these pins. This happens when standard operating system voltages must interface together (i.e., 5 V to 3.3 V systems).

For example, a 5 V control voltage is needed to control the NCP590 operating with  $V_{IN} = 3.6$  V. The input current into the ENx pin can be kept to safe levels by adding a 100 k resistor in series with the 5 V control drive voltage. This will keep the input voltage in compliance with the maximum ratings and will allow control of the output. Use of this setup will affect turn-on time and will increase the enable current higher than the input current specified in the electrical parameter tables.
