

# NCV7361A

## Voltage Regulator with Integrated LIN Transceiver

The NCV7361A consists of a low drop voltage regulator, 5.0 V/50 mA and a LIN bus transceiver. The LIN transceiver is suitable for LIN bus systems compatible to "LIN-Protocol Specification" Rev. 1.3, 2.0 and SAE J2602.

The combination of voltage regulator and bus transceiver make it ideal for a powerful and inexpensive cost effective slave node in a LIN Bus system.

### Features

- Operating Voltage  $V_{SUP} = 5.5$  to 18 V
- Very Low Standby Current Consumption < 110  $\mu$ A in Normal Mode (< 50  $\mu$ A in Sleep Mode)
- LIN-Bus Transceiver:
  - ◆ PNP-Bipolar Transistor Driver
  - ◆ Slew Rate Control and Wave Shaping for Best EMC Behavior
  - ◆ BUS Input Voltage -24 V to 30 V (Independent of  $V_{SUP}$ )
  - ◆ Wake-Up Via LIN Bus
  - ◆ Baud Rate up to 20 kBaud
  - ◆ Compatible to LIN Specification 1.3, 2.0 and SAE J2602
  - ◆ Compatible to ISO9141 Functions
- Wake-Up by LIN BUS and Startup Capable Independent of EN Voltage Level
- Linear Low Drop Voltage Regulator:
  - ◆ Output Voltage 5.0 V  $\pm$  2%
  - ◆ Output Current Max. 50 mA
  - ◆ Output Current Limit
  - ◆ Overtemperature Shutdown
- Reset Time 100 ms and Reset Threshold Voltage 4.65 V
- CMOS Compatible Interface to Microcontroller
- Load Dump Protected (40 V Peak)
- Resistant Against Transient Pulses According to ISO 7637 at Pin  $V_{SUB}$ , BUS and EN
- NCV Prefix for Automotive and Other Applications Requiring Site and Change Control

## PACKAGE PIN DESCRIPTION

Pin	Symbol	Description
1	V <sub>SUP</sub>	Supply voltage.
2	EN	Enable input controls the regulator. Active high.
3	GND	Ground
4	BUS	LIN bus line.
5	RxD	Receive output (push-pull to V <sub>OUT</sub> ).
6	TxD	Transmit input (pullup-input to V <sub>OUT</sub> ).
7	RESET	Reset output, active low (pullup to V <sub>OUT</sub> ).
8	V <sub>OUT</sub>	Regulator output 5.0 V/50 mA.

## ELECTRICAL SPECIFICATIONS

All voltages are referenced to ground (GND). Positive currents flow into the IC.

The maximum ratings (in accordance with IEC 134) given in the table below are limiting values that do not lead to a permanent damage of the device but exceeding any of

these limits may do so. Long term exposure to limiting values may affect the reliability of the device. Correct operating of the device can't be guaranteed if any of these limits are exceeded.

### OPERATING CONDITIONS

Characteristic	Symbol	Min	Max	Unit
Supply Voltage	$V_{SUP}$	5.25	18	V
Operating Ambient Temperature	$T_A$	-40	+125	°C
Junction Temperature	$T_J$	-	+150	°C

### MAXIMUM RATINGS

Rating	Symbol	Condition	Min	Max	Unit
$V_{SUP}$	$V_{SUP}$	-	-1.0	30	V
		$T \leq 500$ ms	-	40	
BUS	$V_{BUS}$	-	-24	30	V
		$T \leq 500$ ms	-	40	
Difference $V_{SUP}-V_{OUT}$	$V_{SUP}-V_{OUT}$	-	-0.3	40	V
EN	$V_{INEN}$	-	-0.3	$V_{SUP} + 0.3$	V
TxD, RxD, $\overline{RESET}$	$V_{IN}$	-	-0.3	$V_{OUT} + 0.3$	V
EN, TxD, RxD, $\overline{RESET}$	$I_{IN}$	-	-25	25	mA
Short Circuit of Pin $V_{SUP}$ and $V_{OUT}$	$I_{INSH}$	-	-500	500	mA
ESD Capability – All Pins	$ESD_{HB}$	Human Body Model, 100 pF via 1.5 k $\Omega$	-2.0	2.0	kV
Junction Temperature	$T_J$	-	-	150	°C
Storage Temperature	$T_{STG}$	-	-55	150	°C
Lead Temperature Soldering Reflow: (SMD styles only)	$T_{slid}$	60 second maximum above 183°C -5°C/+0°C allowable conditions	-	240 peak	°C

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

# NCV7361A

## FUNCTIONAL DESCRIPTION

The NCV7361A consists of a low drop voltage regulator 5.0 V/50 mA and a LIN Bus transceiver, which is a bidirectional bus interface for data transfer between the LIN bus and the LIN protocol controller.

Additionally, the NCV7361A features a  $\overline{\text{RESET}}$  output with a reset delay of 100 ms and a fixed threshold of 4.65 V and Enable (EN) control for the regulator.

### Operating Modes

The NCV7361A provides two main operating modes “normal” and “sleep” and the intermediate states “POR”, “Ini-state” and “thermal shutdown”. The main modes are fixed states defined by basic actions ( $V_{\text{SUP}}$  start, EN or wake-up). The intermediate states are soft states. They aren’t defined by logical actions but by changes of voltage ( $V_{\text{SUB}}$   $V_{\text{OUT}}$ ) or junction temperature.

Figure 15. State Diagram of Operating Modes

### Normal Mode

The whole NCV7361A is active. Switching to normal mode can be done via the following actions:

- Start of  $V_{\text{SUP}}$  or after Undervoltage Reset
- Rising Edge at EN (EN = High) (Local Wake-Up)
- Activity on the LIN Bus (Remote Wake-Up)

### Sleep Mode

Sleep mode is most current saving. With a falling edge on EN (EN = Low) the NCV7361A is switched from normal mode into sleep mode. The voltage regulator will be switched off and the LIN transceiver is in recessive state.

## NCV7361A

**Figure 16. Operating of Power On and Undervoltage RESET**

Switching into sleep mode can be done independently from the current transceiver state. That means if the transmitter is in dominant state this state will be cancelled and it will be switched to recessive state.

### POR-state

This is the power-on-reset state of the NCV7361A, while  $V_{SUP} < V_{SUVR\_OFF}$ . If the prior state was sleep mode, the NCV7361A switches via the Ini-state to normal mode.

### Ini-state

This is an intermediate state, which will pass through after switch-on of  $V_{SUP}$  or  $V_{OUT}$ . The NCV7361A remains in this state if  $V_{OUT}$  is below  $V_{RES}$  (Reset Output = L) and  $V_{SUP} > V_{SUVR\_ON}$ .

### Thermal Shutdown

If the junction temperature  $T_J$  is higher than  $T_{JSHD}$  ( $>155^{\circ}\text{C}$ ), the NCV7361A will be switched into the thermal shutdown mode. The behavior within this mode is comparable with the sleep mode except for LIN transceiver operating. The transceiver is completely disabled, no wake-up functionality is available.

If  $T_J$  falls below the thermal recovery temperature  $T_{JREC}$  (typical  $140^{\circ}\text{C}$ ) the NCV7361A will be recover to the previous state (normal or sleep).

### Initialization

Initialization is started if the power supply is switched on as well as every rising edge on of the NCV7361A via the EN pin.

### $V_{SUP}$ - Power On

If  $V_{SUP}$  is switched on the NCV7361A starts to normal mode via the POR- and Ini-state. A combination of dynamic POR and undervoltage reset circuitry generates a POR signal, which switches the NCV7361A into normal mode. This power on behavior is independent from the status of the EN pin.

Power-on-Reset and undervoltage reset operates independent from each other, which secures the

independence from the rise time of  $V_{SUP}$ . During fast  $V_{SUP}$  edges the Power-on-Reset will be active. If the increasing of  $V_{SUP}$  is very slow ( $> 1 \text{ ms/V}$ ) the undervoltage reset unit initializes the voltage regulator if  $V_{SUP} > V_{SUVR\_OFF}$  (typical 3.5 V).

The effects of both POR circuits at different  $V_{SUP}$  slopes as shown in Figure 16.

After POR the voltage regulator starts and  $V_{OUT}$  will be output. If  $V_{OUT} > V_{MRes}$  the bus interface will be activated. If the  $V_{OUT}$  voltage level is higher than  $V_{RES}$ , the reset time  $t_{Res} = 100 \text{ ms}$  is started. After  $t_{Res}$  the RESET output switches from low to high (Figure 16).

### Start of Linear Regulator via Wake-Up

The initialization is only being done for the  $V_{OUT}$  circuitry parts. This procedure begins with leaving the master reset state ( $V_{OUT} > V_{MRes}$ ) and runs in the same manner as the  $V_{SUP}$  - Power-On.

### Wake-Up

If the regulator is put into sleep mode it can be “waked-up” with the BUS interface. Every pulse on the BUS (high pulse or low pulse) with a pulse width of minimum  $60 \mu\text{s}$  switches on the regulator.

After the BUS has “waked-up” the regulator, it can only be switched off with a high level followed by a low level on the EN pin.

### $V_{SUP}$ Undervoltage Reset

The undervoltage detection unit inhibit an undefined behavior of the NCV7361A under low voltage condition. If  $V_{SUP}$  drops below  $V_{SUVR\_ON}$  (typical 3 V) the undervoltage detection becomes active and the IC will be switched to POR state. The following increasing of  $V_{SUP}$  above  $V_{SUVR\_OFF}$  (typical 3.5 V) cancels this POR state and the voltage regulator starts with the initialization sequence.

### $V_{SUP}$ Undervoltage in Normal Mode

Supply Voltages below  $V_{SUVR\_OFF}$  do not influence the voltage regulator. The output voltage  $V_{OUT}$  follows  $V_{SUP}$

**V<sub>SUP</sub> Undervoltage in Sleep Mode**

No exit from the sleep mode will take place if the V<sub>SUP</sub> voltage drops down to V<sub>SUVR\_ON</sub> (typical 3.0 V). The undervoltage reset becomes active (POR-state). As a result of this operating, the sleep mode is left to the normal mode. If V<sub>SUP</sub> rises again above V<sub>SUVR\_OFF</sub> (typical 3.5 V), the IC initializes the voltage regulator and continues to work with the normal mode.

The undervoltage reset unit secures stable operating in the undervoltage range of V<sub>SUP</sub> down to GND level. The dynamic Power-On-Reset secures a defined internal state independent from the duration of the V<sub>SUP</sub> drop, which secures a stable restart.

**Overtemperature Shutdown**

If the junction temperature is 155°C < T<sub>J</sub> < 170°C the overtemperature recognition will be activated and the regulator voltage will be switched off. The V<sub>OUT</sub> voltage drops down, the reset state is entered and the bus-transceiver is switched off (recessive state).

After T<sub>J</sub> falls below 140°C the NCV7361A will be initialized again (Figure 17) independently from the voltage levels on EN and BUS. Within the thermal shutdown mode the transceiver can not be switched to the normal mode neither with local nor with remote wake-up.

The operation of the NCV7361A is possible between T<sub>Amax</sub> (125°C) and the switch-off temperature, but small parameter differences can appear.

After overtemperature switch-off the IC behaves as described in Figure 17.

**LIN BUS Transceiver**

The NCV7361A is a bidirectional bus interface device for data transfer between the LIN bus and the LIN protocol controller.

The transceiver consists of a pnp-driver (1.2 V @ 40 mA) with slew rate control, wave shaping and current limit, and a high voltage receiver/comparator followed by a filter circuit.

**Transmit Mode**

During transmission the data at the TxD pin will be transferred to the BUS driver for generating a BUS signal. To minimize the electromagnetic emission of the bus line, the BUS driver has integrated slew rate control and wave shaping circuitry.

Transmitting will be interrupted in the following cases:

- Sleep Mode
- Thermal Shutdown Active
- Master Reset (V<sub>OUT</sub> < 3.15 V)

The recessive BUS level is generated from the integrated 30 k pullup resistor in series with a diode. This diode prevents reverse current on V<sub>BUS</sub> when V<sub>BUS</sub> > V<sub>SUP</sub>.

No additional termination resistor is necessary to use the NCV7361A in LIN slave nodes. If this IC is used for LIN master nodes, it is necessary to terminate the bus pin with an external 1.0 kΩ resistor in series with a diode to V<sub>BAT</sub>.

**Receive Mode**

The data signal from the BUS pin will be transferred continuously to the pin RxD. Short spikes on the bus are suppressed by the internal filter circuit (τ = 2.8 μs).

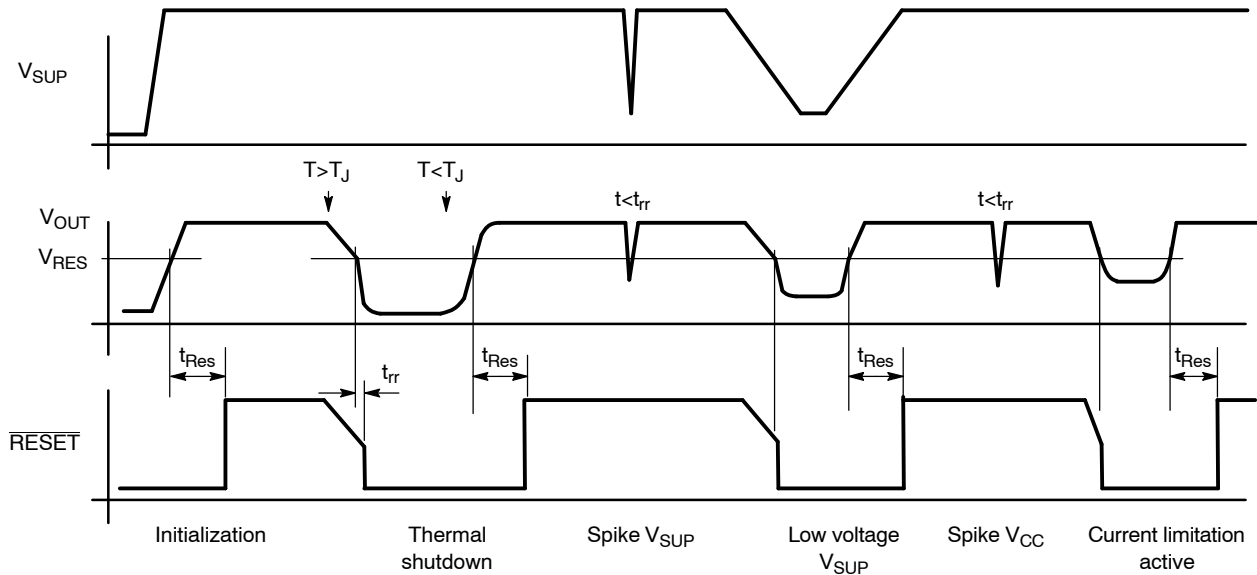

Figure 17. RESET Behavior

# NCV7361A

**Figure 18. Receive Mode Impulse Diagram**

The receive threshold values  $V_{thr\_max}$  and  $V_{thr\_min}$  are symmetrical to  $0.5 \cdot V_{SUP}$  with a hysteresis of  $0.135 \cdot V_{SUP}$ . The LIN specific receive threshold is between  $0.4 \cdot V_{SUP}$  and  $0.6 \cdot V_{SUP}$ .

### Data Rate

The NCV7361A is a *constant slew rate* transceiver. The bus driver works with a fixed slew rate range of  $1.0 \text{ V}/\mu\text{s} \leq \Delta V/\Delta T \leq 2.5 \text{ V}/\mu\text{s}$ . This principle provides good symmetry of the slope times between recessive to dominant and dominant to recessive slopes within the LIN bus load range ( $C_{BUS}$ ,  $R_{term}$ ).

The NCV7361A guarantees data rates up to 20 kb within the complete bus load range under worst case conditions.

The constant slew rate principle holds appropriate voltage levels and can operate within the LIN Protocol Specification for RC oscillator systems with a matching tolerance up to  $\pm 2\%$  between 2 nodes.

### TxD Input

The 5.0 V input TxD directly controls the BUS level:

TxD = low  $\rightarrow$  BUS = low (dominant level)

TxD = high  $\rightarrow$  BUS = high (recessive level)

The TxD pin has an internal pullup resistor connected to  $V_{OUT}$ . This guarantees that an open TxD pin generates a recessive BUS level.

**Figure 19. TxD Input Circuitry**

**RxD Output**

The received BUS signal will be output to the 5.0 V RxD pin:

$$\text{BUS} < V_{\text{thr\_cnt}} - 0.5 * V_{\text{thr\_hys}} \rightarrow \text{RxD} = \text{low}$$

$$\text{BUS} > V_{\text{thr\_cnt}} + 0.5 * V_{\text{thr\_hys}} \rightarrow \text{RxD} = \text{high}$$

This output is a push-pull driver between  $V_{\text{OUT}}$  and GND with an output current capability of 1.0 mA.

**Figure 20. RxD Output Circuitry**

**Linear Regulator**

The NCV7361A has an integrated low dropout linear regulator with a P-Channel MOSFET output driver whose output is  $5.0 \text{ V} \pm 2\%$  at  $\leq 50 \text{ mA}$  and  $5.5 \text{ V} \leq V_{\text{SUP}} \leq 18 \text{ V}$ . Figure 21 shows typical current limit based on the output voltage.

**Figure 21. Characteristic of Current Limit vs. Output Voltage**

**RESET**

$\overline{\text{RESET}}$  switches from low to high if  $V_{\text{SUP}}$  is switched on and  $V_{\text{OUT}} > V_{\text{RES}}$  for  $t_{\text{Res}}$ .

If  $V_{\text{OUT}}$  drops below  $V_{\text{RES}}$ , the  $\overline{\text{RESET}}$  output goes from high to low after  $t_{\text{rr}}$ . Short transients will be filtered.

The  $\overline{\text{RESET}}$  output driver is driven from  $V_{\text{OUT}}$  to guarantee proper operation.

**Figure 22. Output Current of Reset Output vs. V<sub>OUT</sub> Voltage**

**Initialization**

The initialization is started if  $V_{\text{SUP}}$  is switched on. This is independent of the EN pin.

**V<sub>SUP</sub> Power ON**

The NCV7361A starts in the normal mode when  $V_{\text{SUP}}$  is applied [ $>3.15 \text{ V}$  (typical)]. The internal circuitry on  $V_{\text{OUT}}$  as well as the internal regulator starts the initialization with power-on-reset. The voltage regulator is switched on.

If  $V_{\text{OUT}} > V_{\text{POR}}$  the bus-interface will be activated.

If  $V_{\text{OUT}}$  is higher than  $V_{\text{RES}}$ , the reset time  $t_{\text{Res}} = 100 \text{ ms}$  is started. After  $t_{\text{Res}}$  the  $\overline{\text{RESET}}$  output switches from low to high (Figure 22).

The initialization procedure at power on is started independent from the EN state. The regulator can only be turned off with a high level followed by a low level on the EN pin.

**Mode Input EN**

The NCV7361A is switched into the sleep mode when EN goes from high to low. The normal mode will be kept as long as EN = high.

The regulator can be turned off by switching EN high to low independent of the state of the bus-transceiver.

The EN input is internally pulled down to guarantee a low with no connection. In the high state, the pulldown current will be switched off to reduce the quiescent current.

The maximum input voltage is  $V_{\text{SUP}}$ . The threshold is typical 2.1 V and therefore CMOS levels can be used as input signals. Figure 23 shows the internal circuitry of the EN pin.

The EN input is internally pulled down to secure that if this pin is not connected a low level will be generated. It will be used two different pull down current sources for high and low level to minimize the sleep mode current.

# NCV7361A

The 4  $\mu\text{A}$  pulldown current source is used if the input voltage  $V_{\text{IN}} >$  high level voltage  $V_{\text{ENH}}$ . If the input voltage drops below the low level of EN  $V_{\text{ENL}}$ , the second current source is used. The resulting pulldown current in this case is 100  $\mu\text{A}$ .

The wide input voltage range allows different EN control possibilities. If the EN input is connected to an CMOS output of the MCU, a falling edge switches the NCV7361A into sleep mode (the regulator is also switched off). The wake-up is only possible via the bus line.

Figure 23. EN Input Circuitry

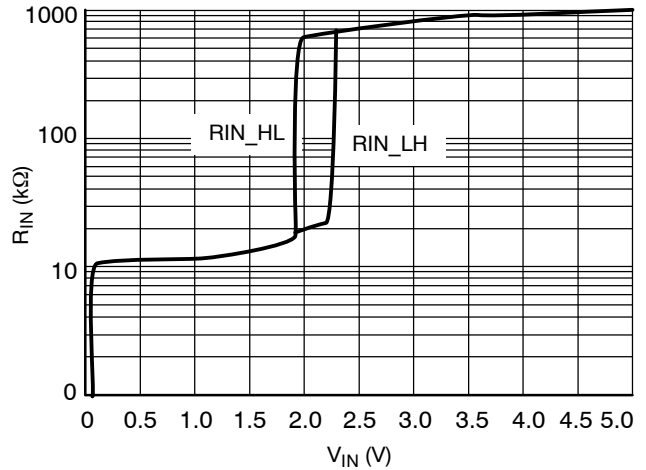

Figure 24.  $R_{\text{IN}}$  Characteristics of EN Input

Figure 25. EN Controlled via MCU

Figure 26. Permanent Normal Mode

## NCV7361A

If the application does not need the wake-up capability of the NCV7361A, a direct connection EN to  $V_{SUP}$  is possible. In this case, the NCV7361A operates in permanent normal mode. Also possible is the external (outside of the module) control of the EN line via a  $V_{BAT}$  signal.

### Wake-Up

If the regulator is in a standby (sleep) mode, it can be woken up with the BUS interface. Every pulse on the BUS (high pulse or low pulse) with a pulse width of minimum 25  $\mu$ s switches on the regulator.

After the BUS wake-up for the regulator, it can only be turned off with a high level followed by a low level on the EN pin.

### Overtemperature Shutdown

The thermal shutdown threshold is  $155^{\circ}\text{C} < T_J < 175^{\circ}\text{C}$ . When exceeded, the overtemperature shutdown will be active and the regulator voltage will be switched off.  $V_{OUT}$  drops down, the reset state is entered and the bus-transceiver is switched off (recessive state).

After  $T_J$  falls below  $140^{\circ}\text{C}$ , the NCV7361A will be initialized (see Figure 17), independent from the voltage levels on EN and BUS. Within the thermal shutdown mode, the transceiver can't be switched to the normal mode with local or with remote wake-up.

Function of the NCV7361A is possible between  $T_{Amax}$  ( $125^{\circ}\text{C}$ ) and the switch-off temperature, but small parameter differences can appear.

After overtemperature switch-off the IC behaves as described in the RESET chapter.

Time Constant of Overall System	τ	1.0	–	5.0	μs

**Recommendations for System Design**

The goal of the LIN physical layer standard is to have a universal definition of the LIN system for plug and play solutions in LIN networks up to 20 kbd bus speeds.

In case of small and medium LIN networks, it's recommended to adjust the total network capacitance to at least 4.0 nF for good EMC and EMI behavior. This can be done by setting only the master node capacitance. The slave node capacitance should have a unit load of typically 220 pF for good EMC/EMI behavior.

In large networks with long bus lines and the maximum number of nodes, some system parameters can exceed the defined limits and the LIN system designer must intervene.

The whole capacitance of a slave node is not only the unit load capacitor itself. Additionally, there is the capacitance of wires and connectors, and the internal capacitance of the LIN transmitter. This internal capacitance is strongly dependent on the technology of the IC manufacturer and should be in the range of 30 pF to 150 pF. If the bus lines have a total length of nearly 40m, the total bus capacitance can exceed the LIN system limit of 10 nF.

A second parameter of concern is the integrated slave termination resistor tolerance. If most of the slave nodes have a slave termination resistance near by the allowed maximum of 60 kΩ, the total network resistance is more

than 700 Ω. Even if the total network capacitance is below or equal to the maximum specified value of 10 nF, the network time constant is higher than 7.0 μs.

This problem can be solved only by adjusting the master termination resistor to the required maximum network time constant of 5.0 μs (max).

The LIN bus output driver of the NCV7361A provides a higher drive capability than necessary (40 mA @ 1.2 V) within the LIN standard (33.6 mA @ 1.2 V). With this driver stage the system designer can increase the maximum LIN networks with a total network capacitance of more than 10 nF. The total network resistance can be decreased to:

$$R_{t\text{t\_min}} = (V_{\text{Bat\_max}} - V_{\text{BUSdom}}) / I_{\text{BUS\_max}} \\ = (18 \text{ V} - 1.2 \text{ V}) / 40 \text{ mA} = 420 \text{ } \Omega$$

*NOTE: The NCV7361A meets the requirements for implementation in RC-based slave nodes. The LIN Protocol Specification requires the deviation of the slave node clock to the master node clock after synchronization must not differ by more than ±2%.*

*Setting the network time constant is necessary in large networks (primary resistance) and also in small networks (primary capacitance).*

MIN/MAX SLOPE TIME CALCULATION

Figure 27. Slope Time Calculation

The slew rate of the bus voltage is measured between 40% and 60% of the output voltage swing (linear region). The output voltage swing is the difference between dominant and recessive bus voltage.

$$dV/dt = 0.2 * V_{swing} / (t_{40\%} - t_{60\%})$$

The slope time is the extension of the slew rate tangent until the upper and lower voltage swing limits:

$$t_{slope} = 5 * (t_{40\%} - t_{60\%})$$

The slope time of the recessive to dominant edge is directly determined by the slew rate control of the transmitter:

$$t_{slope} = V_{swing} / dV/dt$$

The dominant to recessive edge is influenced from the network time constant and the slew rate control, because it's a passive edge. In case of low battery voltages and high bus loads the rising edge is only determined by the network. If the rising edge slew rate exceeds the value of the dominant one, the slew rate control determines the rising edge.

**Power Dissipation and Operating Range**

The max power dissipation depends on the thermal resistance of the package and the PCB, the temperature difference between Junction and Ambient as well as the airflow.

The power dissipation can be calculated with:

$$P_D = (V_{SUP} - V_{OUT}) * I_{VOUT} + P_{D\_TX}$$

The power dissipation of the transmitter  $P_{D\_TX}$  depends on the transceiver configuration and its parameters as well as on the bus voltage  $V_{BUS} = V_{BAT} - V_D$ , the resulting termination resistance  $R_L$ , the capacitive bus load  $C_L$  and the bit rate. Figure 28 shows the dependence of power dissipation of the transmitter as function of  $V_{SUP}$ . The conditions for calculation the power dissipation was:  $R_L = 500 \Omega$ ,  $C_L = 10 \text{ nF}$ , Bitrate = 20 kbit and duty cycle on TxD of 50%.

Figure 28. Power Dissipation LIN Transceiver @ 20 kbit

The permitted package power dissipation can be calculated:

$$P_{Dmax} = \frac{T_J - T_A}{R_{\theta J-A}}$$

If we consider that  $P_{D\_TX\_max} = f(V_{SUP})$ , it can be calculated the max output current  $I_{VOUT}$  on  $V_{OUT}$ :

$$I_{VOUTmax} = \frac{\frac{T_J - T_A}{R_{\theta J-A}} - P_{D\_TX\_max} @ V_{SUP}}{V_{SUP} - V_{OUT}}$$

$T_J - T_A$  is the temperature difference between junction and ambient, and  $R_{th}$  is the thermal resistance of the package. The thermal energy is transferred via the package and the pins to the ambient. This transfer can be improved with additional ground areas on the PCB as well as ground areas under the IC.

\*Bold face items in the tables above represent the package without the external thermal system.

The Cauer networks generally have physical significance and may be divided between nodes to separate thermal behavior due to one portion of the network from another. The Foster networks, though when sorted by time constant (as above) bear a rough correlation with the Cauer networks, are really only convenient mathematical models. Cauer networks can be easily implemented using circuit

simulating tools, whereas Foster networks may be more easily implemented using mathematical tools (for instance, in a spreadsheet program), according to the following formula:

$$R(t) = \sum_{i=1}^n R_i (1 - e^{-t/\tau_i})$$

**Figure 32. SO-8 Thermal Transient Response on Typical Test Boards**

**Figure 33. SO-8 Thermal Duty Cycle Curves on 1.0 in. Spreader Test Board**

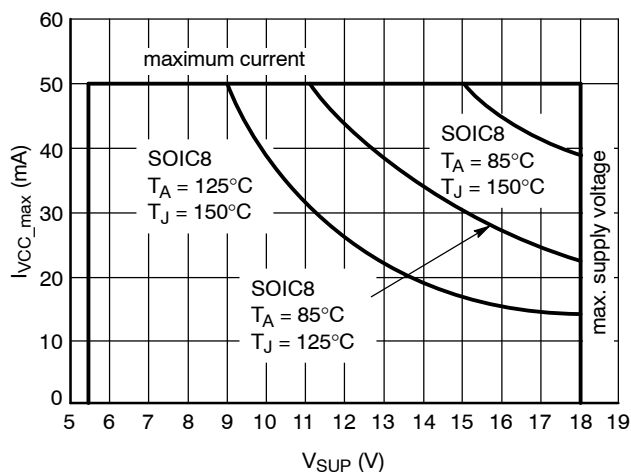

Figure 34. Safe Operating Area

The linear regulator of the NCV7361A operates with input voltages up to 18 V and can output a current of 50 mA. The maximum power dissipation limits the maximum output current at high input voltages and high ambient temperatures. The output current of 50 mA at an ambient temperature of  $T_A = 125^\circ C$  is only possible with small voltage differences between  $V_{SUP}$  and  $V_{CC}$ . See Figure 34 for safe operating areas for different ambient and junction temperatures.

**Regulator Circuitry**

**Low Dropout Regulator**

The voltage regulator of the NCV7361A is a low dropout regulator (LDO) with a P-MOSFET as the driving transistor.

This type of regulator has a standard pole, generated from the internal frequency compensation and an additional pole, which is dependent from the load and the load capacity. This additional pole can cause an instable behavior of the regulator! It requires a zero point to compensate this additional pole. It can be realized via an additional load resistor in series with a load capacity. It is used for this compensation the Equivalent Series Resistance (ESR) of the load capacity. Every real capacity is characterized with an ESR value. With the help of this ESR value an additional zero point is implemented into the amplification loop and therefore the result of the negative phase shift is compensated.

Because of this correlation the regulator has a stable operating area which is defined by the load resistance  $R_L$ , the load capacity  $C_L$  and the corresponding ESR value. The load resistance resp. load current is defined by the application itself and therefore the compensation of the pole can only be done via variation of the load capacity and ESR value.

**Input Capacity on  $V_{SUP}$   $C_{IN}$**

It is necessary to have an input capacity of  $C_{IN} = 4.7 \mu F$ . Higher capacity values improve the line transient response and the supply noise rejection behavior. The combination of electrolytic capacity (e.g. 100  $\mu F$ ) in parallel with a ceramic RF-capacity (e.g. 100 nF) archives good disturbance suppressing.

The input capacity should be placed as close as possible (< 1 cm) to the  $V_{SUP}$  pin.

**Load Capacity on  $V_{OUT}$   $C_L$**

The regulator is stabilized by the output capacitor  $C_L$ . The NCV7361A requires a minimum of 4.7  $\mu F$  capacity connected to the 5.0 V output to insure stability. This capacitor should maintain its ESR in the stable region of the ESR curve (Figure 35) over the full operating temperature range of the application. The capacity value and the ESR of a capacitor changes with temperature. The minimal capacity value must be kept within the whole operating temperature range.

**Example 1:**

The regulator is stabilized using a 47  $\mu F$  aluminum electrolytic capacitor load (ESR = 0.7  $\Omega$  @ 25 $^\circ C$ ). The capacitance decreases to 42  $\mu F$  and the ESR increases to 8.9  $\Omega$  at an ambient temperature of -40 $^\circ C$ . The ESR value is located in the unstable region. The regulator will be unstable at -40 $^\circ C$ .

**Example 2:**

The regulator is stabilized using a 47  $\mu F$  tantalum capacitor load (ESR = 0.1  $\Omega$  @ 25 $^\circ C$ ). The capacitance decreases to 45  $\mu F$  and the ESR increases to 0.11  $\Omega$  at an ambient temperature of -40 $^\circ C$ . The ESR value is located in the stable region. The regulator will be stable at -40 $^\circ C$ .

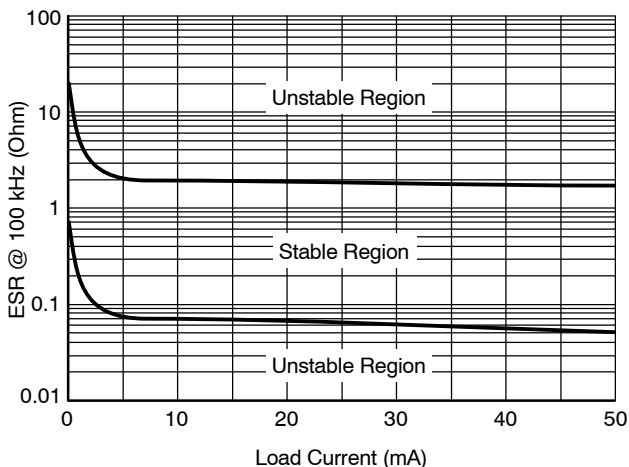

Figure 35. ESR Curves for  $6.8 \mu F \leq C_L \leq 100 \mu F$  and Frequency of 100 kHz

The value and type of the output capacitor can be selected by using the diagram shown in Figure 35.

**Capacity Value**

The capacity value of an electrolytic capacitor is dependence from the voltage, temperature and the frequency. The temperature coefficient of the capacity value is positive, that means that the value increases with increasing of the temperature. The capacity value decreases with increasing of the frequency. This behavior of a capacitor can cause that at  $T_A = -40^{\circ}\text{C}$  the capacity value falls below the minimum required capacity for the regulator. In this case the regulator becomes instable, which means the regulator starts oscillation. The nominal value of the capacitor at  $T_A = 25^{\circ}\text{C}$  has to be chosen with enough margin under consideration of the capacitor specification. The instable behavior will be amplified because of the decreasing of the capacity with this oscillation.

**ESR**

The Equivalent Serial Resistance is the resistor part of the equivalent circuit diagram of a capacitor. The ESR value is dependent from the temperature and frequency.

Normally the specified ESR values for a capacitor is valid at a temperature of  $T_A = 25^{\circ}\text{C}$  and a frequency of  $f = 100\text{ kHz}$ .

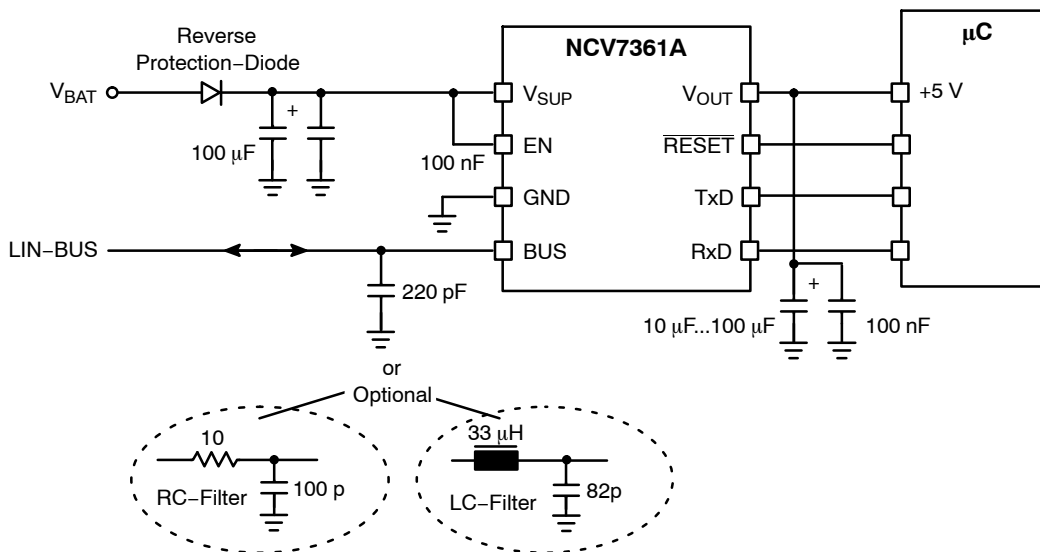

The temperature coefficient is negative, which means with increasing of the temperature the ESR value decreases. In the choice of the capacity has to be taken into account that the ESR can decrease at  $T_A = -40^{\circ}\text{C}$  dramatically that the valid operating area can be left, which causes that the regulator will be instable.

**Tantalum Capacitors**

This type of capacitor has a low dependence of the capacity and the ESR from the temperature and is therefore well suitable as  $V_{\text{OUT}}$  load capacity.

**Aluminum Capacitors**

These capacitors show a strong influence of the capacity and the ESR from the temperature. These characteristic restrains the usability as load capacity for the low drop regulator of NCV7361A.

**Figure 36. Application Circuit (Slave Node)**

**EMI Suppressing**

To minimize the influence of EMI from the bus line, a 220 pF capacitor should be directly connected to the BUS pin (see Figure 36).

The value of the filter capacity can be adjusted to the size of the LIN network. 220 pF should be used for bigger networks. Values from 333 pF up to 1.0 nF should be used for middle to small LIN networks. Finally the size of the

filter capacitor influences the effectiveness of the EMI suppressing in conformance to the maximum LIN bus capacity of 10 nF.

LC-filters or RC-filters can also be used. The value of C, L or R, depends on the corner frequency, the maximum LIN bus capacity (10 nF) and the compliance with the DC- and AC LIN bus parameters.

Figure 37. Application Circuit for LIN Sub-Bus with NCV7361A as Slave Node

## NCV7361A

### Connection to Flash–MCU

During programming of a flash MCU the NCV7361A should be disconnected from the MCU. This can be done by disconnecting the supply voltage of the NCV7361A or by turning off the NCV7361A with the EN pin. A blocking

diode must be used between the MCU and the RxD pin to avoid loading of the programming data.

The programming of the flash is also possible via the LIN pin, if the MCU supports this kind of flash mode.

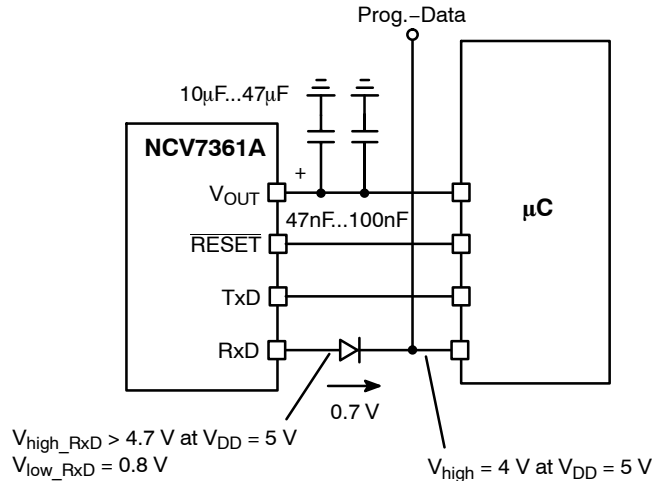

Figure 38. Example Circuitry for Connection of RxD to MCU for Flash Programming

### Operating During Disturbance

#### Operating Without $V_{\text{SUP}}$ or GND

The BUS pin is designed for voltages of GND – 24 V up to GND + 30 V. This prevents loss of communication between other bus nodes with the loss of  $V_{\text{SUP}}$  or loss of GND. The BUS pin will remain at  $V_{\text{BAT}}$  and current draw will be minimal with the loss of GND or  $V_{\text{SUP}}$ .

#### Short Circuit BUS to $V_{\text{BAT}}$

- Recessive LIN bus is blocked, no influence to the NCV7361A
- Dominant Current limit, thermal shutdown of NCV7361A if power dissipation raises  $T_{\text{J}}$

#### Short Circuit BUS to GND

The LIN bus is blocked. There is no influence to the NCV7361A.

#### Short Circuit TxD to GND

The LIN transceiver is permanent in the dominant state as is the LIN bus. This state can only be detected from the LIN controller. In this case the controller must switch-off the LIN node via the EN input of the NCV7361A and look for a recessive state. A thermal shutdown of NCV7361A will appear if the thermal shutdown threshold is exceeded.

#### TxD Open

The internal pullup resistor forces the LIN node to the recessive state. The communication between the other bus-nodes will not be disturbed.

#### Short Circuit $V_{\text{OUT}}$ to GND

The  $V_{\text{OUT}}$  pin is protected via a current limit. This state is comparable with the behavior in the sleep mode.

#### Overload of $V_{\text{OUT}}$

##### Thermal Switch-Off

The power dissipation is increasing if the load current is between  $I_{\text{VOUT\_max}}$  and  $I_{\text{LVOUT}}$ . If the IC exceeds the thermal shutdown threshold of  $> 155^{\circ}\text{C}$ , the transceiver will be switched off. The voltage regulator will also be switched off and a reset signal is forced.

##### Overcurrent

If the current limit is active the voltage on  $V_{\text{OUT}}$  drops down. If this voltage is below the threshold  $V_{\text{RES}}$ , a reset will be forced.

#### Undervoltage $V_{\text{SUP}}$ , $V_{\text{OUT}}$

The reset circuit guarantees the correct behavior of the driver during undervoltage. The BUS pin generates the recessive state if  $V_{\text{OUT}} < V_{\text{MRes}}$ . The inputs EN and TxD have pull-down and pull-up circuits respectively.

If  $V_{\text{MRes}} \leq V_{\text{OUT}} \leq 4.5 \text{ V}$  the TxD signal is transmitted to the bus. The receive mode is also active.

#### Short Circuit RxD, RESET to GND or $V_{\text{OUT}}$

Both outputs are short circuit proof to  $V_{\text{OUT}}$  and ground.

# NCV7361A

## ESD/EMC Remarks

### General Remarks

Electronic semiconductor products are sensitive to Electro Static Discharge (ESD). Always observe Electro Static Discharge control procedures whenever handling semiconductor products.

### ESD Test

The NCV7361A is tested according to MIL883–3015.7 (Human Body Model).

### EMC

The test on EMC impacts is done according to ISO 7637–1 for power supply pins and ISO 7637–3 for data and signal pins.

## POWER SUPPLY PIN V<sub>SUP</sub>

Test Pulse	Condition	Duration
1	$t_1 = 5.0 \text{ s}/U_S = -100 \text{ V}/t_D = 2.0 \text{ ms}$	5000 Pulses
2	$t_1 = 0.5 \text{ s}/U_S = 100 \text{ V}/t_D = 0.05 \text{ ms}$	5000 Pulses
3a/b	$U_S = -150 \text{ V}/U_S = 100 \text{ V}$ Burst 100 ns/10 ms/90 ms Break	1 h
5	$R_i = 0.5 \Omega, t_D = 400 \text{ ms}$ $t_r = 0.1 \text{ ms}/U_P + U_S = 40 \text{ V}$	10 Pulses Every 1 Min

## DATA AND SIGNAL PINS EN, BUS

Test Pulse	Condition	Duration
1	$t_1 = 5.0 \text{ s}/U_S = -100 \text{ V}/t_D = 2.0 \text{ ms}$	1000 Pulses
2	$t_1 = 0.5 \text{ s}/U_S = 100 \text{ V}/t_D = 0.05 \text{ ms}$	1000 Pulses
3a/b	$U_S = -150 \text{ V}/U_S = 100 \text{ V}$ Burst 100 ns/10 ms/90 ms Break	1000 Burst

# NCV7361A

## PACKAGE DIMENSIONS

SOIC-8 NB  
CASE 751-07  
ISSUE AH

**NOTES:**

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: MILLIMETER.
3. DIMENSION A AND B DO NOT INCLUDE MOLD PROTRUSION.
4. MAXIMUM MOLD PROTRUSION 0.15 (0.006) PER SIDE.
5. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.127 (0.005) TOTAL IN EXCESS OF THE D DIMENSION AT MAXIMUM MATERIAL CONDITION.
6. 751-01 THRU 751-06 ARE OBSOLETE. NEW STANDARD IS 751-07.

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	4.80	5.00	0.189	0.197
B	3.80	4.00	0.150	0.157
C	1.35	1.75	0.053	0.069
D	0.33	0.51	0.013	0.020
G	1.27 BSC		0.050 BSC	
H	0.10	0.25	0.004	0.010
J	0.19	0.25	0.007	0.010
K	0.40	1.27	0.016	0.050
M	0 °	8 °	0 °	8 °
N	0.25	0.50	0.010	0.020
S	5.80	6.20	0.228	0.244

### SOLDERING FOOTPRINT\*

\*For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

ON Semiconductor and are registered trademarks of Semiconductor Components Industries, LLC (SCILLC). SCILLC reserves the right to make changes without further notice to any products herein. SCILLC makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does SCILLC assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. "Typical" parameters which may be provided in SCILLC data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. SCILLC does not convey any license under its patent rights nor the rights of others. SCILLC products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the SCILLC product could create a situation where personal injury or death may occur. Should Buyer purchase or use SCILLC products for any such unintended or unauthorized application, Buyer shall indemnify and hold SCILLC and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that SCILLC was negligent regarding the design or manufacture of the part.
