

SYNCHRONOUS-BUCK PWM CONTROLLER WITH NMOS LDO CONTROLLER

FEATURES

- **Switching Mode Step-Down dc-to-dc Controller With Fast LDO Controller**
- **Input Voltage Range**
 Switcher: 4.5 V to 28 V
 LDO: 1.1 V to 3.6 V
- **Output Voltage Range**
 Switcher: 0.9 V to 3.5 V
 LDO: 0.9 V to 2.5 V
- **Synchronous for High Efficiency**
- **Precision V_{REF} ($\pm 1\%$)**
- **PWM Mode Control: Max. 500-kHz Operation**
- **High-Speed Error Amplifier**
- **Overcurrent Protection With Temperature Compensation Circuit**
- **Overvoltage and Undervoltage Protection**
- **Programmable Short-Circuit Protection**

APPLICATIONS

- **Notebook PCs, PDAs**
- **Consumer Game Systems**
- **DSP Application**

DESCRIPTION

The TPS5110 provides one PWM-mode synchronous buck regulator controller (SBRC) and one low drop-out (LDO) regulator controller. The TPS5110 supports a low-voltage/high-current power supply for I/O and other peripherals in modern digital systems. The SBRC of the TPS5110 automatically adjusts from PWM mode to SKIP mode to maintain high efficiency under all load conditions. The LDO controller drives an external N-channel power MOSFET that realizes fast response and ultra-low dropout voltage. A unique overshoot protection circuit prevents a voltage hump at fast load decreasing transients. The current protection circuit for SBRC detects the drain-to-source voltage drop across the low-side and high-side power MOSFET while it is conducting. Also, the current protection circuit has a temperature coefficient to compensate for the $R_{DS(on)}$ variation of the MOSFET. This resistor-less current protection simplifies the system design and reduces the external parts count. The LDO controller includes current-limit protection. Other features, such as undervoltage lockout, power good, overvoltage, undervoltage, and programmable short-circuit protection promote system reliability.

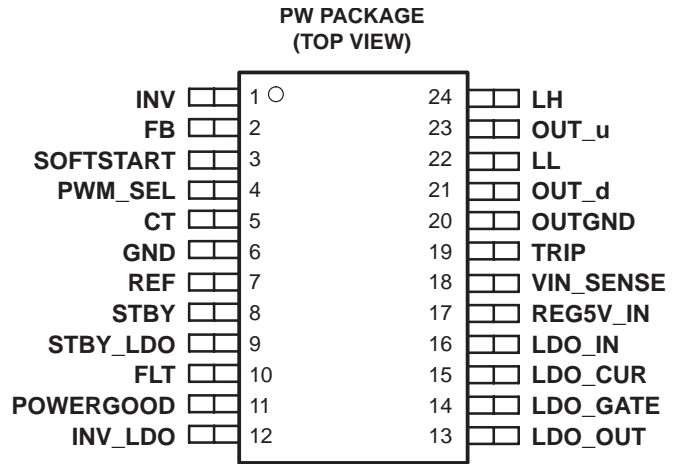

SIMPLIFIED APPLICATION

ORDERING INFORMATION

Terminal Functions

TERMINAL		I/O	DESCRIPTION
NAME	NO.		
CT	5	I/O	External capacitor from CT to GND adjusts frequency of the triangle oscillator.
FB	2	O	Feedback output of error amplifier
FLT	10	I/O	Fault latch timer pin. An external capacitor is connected between FLT and GND to set the FLT enable time up.
GND	6	–	Signal GND
INV	1	I	Inverting input of the SBRC error amplifier, skip comparator, OVP/UVLP comparators and POWERGOOD comparator
INV_LDO	12	I	Inverting input of the LDO regulator, OVP/UVLP comparators and POWERGOOD comparator
LDO_CUR	15	I	Current sense input of the LDO regulator.
LDO_GATE	14	O	Gate control output of an external MOSFET for LDO
LDO_OUT	13	I/O	LDO regulator's output connection. If output voltage causes an over shoot at output current changes high to low quickly, it pulls out electrical charge from this pin.
LDO_IN	16	I	Input of LDO regulator and current sense input of LDO regulator
LH	24	I/O	Bootstrap capacitor connection for high-side gate driver
LL	22	I/O	High side gate driving return. Connect this pin to the junction of the high side and low side MOSFET(s) for floating drive configuration. This pin also is an input terminal for current comparator.
OUT_d	21	O	Gate drive output for low-side MOSFET(s)
OUT_u	23	O	Gate drive output for high-side MOSFET(s).
OUTGND	20	–	Ground for FET drivers. It is connected to the current limiting comparator's negative input.
POWERGOOD	11	O	Power good open-drain output. PG comparators monitor both SBRC's and LDO's over voltage and under voltage. The threshold is $\pm 7\%$. When either output is beyond this condition, POWERGOOD output goes low. When STBY or STBY_LDO goes high, the POWERGOOD pin's output starts with high. POWERGOOD also monitors REG5V_IN's UVLO output.
PWM_SEL	4	I	PWM or auto PWM/SKIP modes select. H: auto PWM/SKIP L: PWM fixed
REF	7	O	0.85-V reference voltage output. This 0.85-V reference voltage is used for setting the output voltage and the voltage protections. This reference voltage is regulated from REG5V_IN power supply.
REG5V_IN	17	I	External 5-V input. This input is a supply voltage for internal circuits.
SOFTSTART	3	I/O	External capacitor between SOFTSTART and GND sets SBRC soft-start time.
STBY	8	I	Standby control input for SBRC. SBRC can be switched into standby mode by grounding the STBY pin.
STBY_LDO	9	I	Standby control input for LDO regulator. LDO regulator can be switched into standby mode by grounding the STBY_LDO pin.
TRIP	19	I	External resistor connection for SBRC's output current protection control.
VIN_SENSE	18	I	SBRC supply voltage monitor. Input range is 4.5 V to 28 V. This pin is for reference of current limit.

FUNCTIONAL BLOCK DIAGRAM

Figure 1. Block Diagram

DETAILED DESCRIPTION

PWM operation

The SBRC block has a high-speed error amplifier to regulate the output voltage of the synchronous buck converter. The output voltage of the SBRC is fed back to the inverting input (INV) of the error amplifier. The noninverting input is internally connected to a 0.85 V precise band gap reference circuit. The unity-gain bandwidth of the amplifier is 2.5 MHz. This decreases the amplifier delay during fast-load transients and contributes to a fast response. Loop gain and phase compensation is programmable by an external C, R network between the FB and INV pins. The output signal of the error amplifier is compared with a triangular wave to achieve the PWM control signal. The oscillation frequency of this triangular wave sets the switching frequency of the SBRC and is determined by the capacitor connected between the CT and GND pins. The PWM mode is used for the entire load range if the PWM_SEL pin is set LOW, or used in high-output current condition if auto PWM/SKIP mode is selected by setting the same pin to HIGH.

SKIP mode operation

The PWM_SEL pin selects either the auto PWM/SKIP mode or fixed PWM mode. If this pin is lower than 0.3 V, the SBRC operates in the fixed PWM mode. If 2.5 V (min.) or higher is applied, it operates in auto PWM/SKIP mode. In the auto PWM/SKIP mode, the operation changes from constant frequency PWM mode to an energy-saving SKIP mode automatically in accordance with load conditions. Using a MOSFET with ultra-low $R_{DS(on)}$ if the auto SKIP function is implemented is not recommended. The SBRC block has a hysteretic comparator to regulate the output voltage of the synchronous buck converter during SKIP mode. The delay from the comparator input to the driver output is typically 1.2 μ s. In the SKIP mode, the frequency varies with load current and input voltage.

high-side driver

The high-side driver is designed to drive high current and low $R_{DS(on)}$ N-channel MOSFET(s). The current rating of the driver is 1.2 A at source and sink. When configured as a floating driver a 5-V bias voltage is delivered from external REG5V_IN supply. The instantaneous-drive current is supplied by the flying capacitor between the LH and LL pins since a 5-V power supply does not usually have low impedance. It is recommended to add a 5- Ω to 10- Ω resistor between the gate of the high-side MOSFET(s) and the OUT_u pin to suppress noise. The maximum voltage that can be applied between the LH and OUTGND pins is 33 V. When selecting the high-current rating MOSFET(s), it is important to pay attention to both gate-drive power dissipation and the rise/fall time against the dead-time between high-side and low-side drivers. The gate-drive power is dissipated from the controller device and it is proportional to the gate charge at $V_{gs} = 5$ V, PWM switching frequency and the numbers of all MOSFETs used for low-side and high-side switches. This gate drive loss should not exceed the maximum power dissipation of the device.

low-side driver

The low-side driver is designed to drive high-current and low $R_{DS(on)}$ N-channel MOSFET(s). The maximum drive voltage is 5 V from REG5V_IN pin. The current rating of the driver is typically 1.5 A at source and sink. Gate resistance is not necessary for the low-side MOSFET for switching noise suppression since it turns on after the parallel diode is turned on (ZVS). It needs the same dissipation consideration when using high-current rating MOSFET(s). Another issue that needs precaution is the gate threshold voltage. Even though the OUT_d pin is shorted to the OUTGND pin with low resistance when the low-side MOSFET(s) is OFF, high dv/dt at the LL pin during turnon of the high side arm generates voltage peak at the OUT_d pin through the drain to gate capacitance, C_{dg} , of the low-side MOSFET(s). To prevent a short period shoot-through during this switching event, the application designer should select MOSFET(s) with adequate threshold voltage.

DETAILED DESCRIPTION

dead time

The internally defined dead-time prevents shoot-through current flowing through the main power MOSFETs during switching transitions. Typical value of the dead-time is 100 ns.

standby

The SBRC and the LDO controller can be switched into standby mode separately by grounding the STBY pin and/or SYBY_LDO pins. The standby-mode current, when both controllers are off, can be as low as 1 nA.

Table 1. Standby Logic ($V_{REG5V_IN} > 4\text{ V}$)†

STBY	STBY_LDO	SBRC	LDO	POWERGOOD
L	L	OFF	OFF	OFF
L	H	OFF	ON	OFF
H	L	ON	OFF	OFF
H	H	ON	ON	ON

soft start

Soft-start ramp up of the SBRC is controlled by the SOFTSTART pin voltage. After the STBY pin is raised to a HIGH level, an internal current source charges up an external capacitor connected between the SOFTSTART and GND pins. The output voltage ramps up as the SOFTSTART pin voltage increases from 0 V to 0.85 V. The soft-start time is easily calculated by the supply current and the capacitance value (see application information). The soft-start timing circuit for the LDO is integrated into the device. The soft-start time is fixed and can be as short as 600 μs . This is observed when the LDO is turned on separately from the SBRC. Simultaneous start up of the two outputs is also possible. Tie the LDO input to the SBRC's output and let both STBY_LDO and STBY voltages rise to the HIGH level simultaneously, then the LDO's output follows the ramp of the SBRC's output.

over current protection

Over current protection (OCP) is achieved by comparing the drain-to-source voltage of the high-side and low-side MOSFET to a set-point voltage, which is defined by both the internal current source, I_{TRIP} , and the external resistor connected between the VIN_SENSE and TRIP pins. I_{TRIP} has a typical value of 13 μA at 25°C. When the drain-to-source voltage exceeds the set-point voltage during low-side conduction, the high-side current comparator becomes active, and the low-side pulse is extended until this voltage comes back below the threshold. If the set-point voltage is exceeded during high-side conduction in the following cycle, the current-limit circuit terminates the high-side driver pulse. Together this action has the effect of decreasing the output voltage until the under voltage protection circuit is activated to latch both the high-side and low-side drivers OFF. In the TPS5110, trip current I_{TRIP} also has a temperature coefficient of 3400 ppm/°C in order to compensate for temperature drift of the MOSFET on-resistance.

DETAILED DESCRIPTION

OCP for the LDO

To achieve the LDO current limit, a sense resistor must be placed in series with the N-channel MOSFET drain, connected between the LDO_IN and LDO_CUR pins (see reference schematic). If the voltage drop across this sense resistor exceeds 50 mV, the output voltage is reduced to approximately 22% of the nominal value, thus activates UVP to start the FLT latch timer. When the time is up, the LDO_GATE pin is pulled LOW to makes the LDO regulator shutdown. Note that the SBRC is also latched OFF at the same time since the LDO and the SBRC share the same FLT capacitor.

overvoltage protection

For over voltage protection (OVP), the TPS5110 monitors the INV and INV_LDO pin voltages. When the INV or INV_LDO pin voltage is higher than 0.95 V (0.85 V +12%), the OVP comparator output goes low and the FLT timer starts to charge an external capacitor connected to FLT pin. After a set time, the FLT circuit latches the high-side and low-side MOSFET drivers and the LDO. The latched state of each block is summarized in Table 2. The timer-source current for the OVP latch is 125 μA(typ.), and the time-up voltage is 1.185 V (typ.). The OVP timer is designed to be 50 times faster than the undervoltage protection timer described below.

Table 2. Overvoltage Protection Logic

OVP OCCURS AT	HIGH-SIDE MOSFET DRIVER	LOW-SIDE MOSFET DRIVER	LDO
SBRC	OFF	ON	OFF
LDO	OFF	OFF	OFF

undervoltage protection

For under voltage protection (UVP), the TPS5110 monitors the INV and INV_LDO pin voltages. When the INV or INV_LDO pin voltage is lower than 0.55 V (0.85 V – 35 %), the UVP comparator output goes low, and the FLT timer starts to charge the external capacitor connected to FLT pin. Also, when the current comparator triggers the OCP, the UVP comparator detects the under-voltage output and starts the FLT capacitor charge, too. After a set time, the FLT circuit latches all of the MOSFET drivers to the OFF state. The timer-latch source current for UVP is 2.3 μA (typ.), and the time-up voltage is also 1.185 V (typ.). The UVP function of the LDO controller is disabled when voltage across the pass transistor is less than 0.23 V (typ.).

FLT

When an OVP or UVP comparator output goes low, the FLT circuit starts to charge the FLT capacitor. If the FLT pin voltage goes beyond a constant level, the TPS5110 latches the MOSFET drivers. At this time, the state of MOSFET is different depending on the OVP alert and the UVP alert, see Table 2. The enable time used to latch the MOSFET drivers is decided by the value of the FLT capacitor. The charging constant current value depends on whether it is an OVP alert or a UVP alert as shown in the following equation:

$$FLT_{source\ current\ (OVP)} = FLT_{source\ current\ (UVP)} \times 50$$

DETAILED DESCRIPTION

undervoltage lockout (UVLO)

When the REG5V_IN voltage decreases below about 4 V, the output stages of both the SBRC and the LDO are turned off. This state is not latched and the operation recovers immediately after the input voltage becomes higher than the turn-on value again. The typical hysteresis voltage is 100 mV.

UVLO for LDO

The LDO_IN voltage is monitored with a hysteretic comparator. When this voltage is less than 1 V, the UVLO circuit disables the UVP/OVP comparators that monitor the INV_LDO voltage. In case the SBRC over current protection is activated prior to that of the LDO's, this protection function may also be observed.

LDO control

The LDO controller can drive an external N-channel MOSFET. This realizes a fast response as well as an ultra-low dropout voltage regulator. For example, it is easy to configure both a 1.8-V and a 1.5-V high-current power supply for core and I/O of modern digital processors, one from the SBRC and the other from the LDO. The LDO_IN voltage range is from 1.1 V to 3.6 V, and the output voltage is adjustable from 0.9 V to 2.5 V by an external resistor divider. Gain and phase of the high-speed error amplifier for this LDO control is internally compensated and is connected to the 0.85-V band-gap reference circuit. The gate driver buffer is supplied by VIN_SENSE voltage. In the relatively high-output voltage applications, make sure that output voltage plus threshold voltage of the pass transistor is less than the minimum VIN. More precisely,

$$V_{\text{VIN_SENSE}} - 0.7 \text{ V} \geq V_{\text{THN}} + V_{\text{LDO_OUT}}$$

where V_{THN} is the threshold voltage of N-channel MOSFET.

The LDO controller is also equipped with OVP, UVP, over current limit and overshoot protection functions.

overshoot protection – LDO

In the event that load current changes from high to low very quickly, the LDO regulator output voltage may start to overshoot. In order to resist this phenomenon, the LDO controller has an overshoot protection function. If the LDO regulator output overshoots, the controller draws electrical charge out from LDO_OUT pin to hold it stable.

DETAILED DESCRIPTION

powergood

A single powergood circuit monitors the SBRC output voltage, LDO output voltage and REF5V_IN voltage. The POWERGOOD pin is an open-drain output. When INV or INV_LDO voltage go beyond +/- 7% of 0.85 V or the REG5V_IN voltage is lower than 4 V, the POWERGOOD pin is pulled down to the LOW level. POWERGOOD propagation delay is minimal, 1 μs to 4 μs.

APPLICATION INFORMATION

The design shown in this application information is a reference design for a notebook PC application. An evaluation module (EVM) is available for customer testing and evaluation. This information allows a customer to fully evaluate the given design using the plug-in EVM shown in Figure 17. For subsequent board revisions, the EVM design can be copied onto the system PCB to shorten the design cycle.

The following key design procedures aid in the design of the notebook PC power supply using TPS5110. An optional circuit composed of Q04, R16, R22 and R24 can be used to increase temperature coefficient of the trip current, which is at the top in the page 18.

output voltage setpoint calculation

The reference voltage and the voltage divider set the output voltage. In the TPS5110, the reference voltage is 0.85 V, and the divider is composed of three resistors in the EVM design that are R01A, R01B and R03 for switching regulator output; R10, R11 and R09 for LDO regulator output.

$$V_O = \frac{R1 \times V_{REF}}{R2} + V_{REF} \text{ or } R2 = \frac{R1 \times V_{REF}}{V_O - V_{REF}}$$

where R1 is the top resistor (kΩ) (R01A + R01B or R10 + R11); R2 is the bottom resistor (kΩ) (R03 or R09); V_O is the required output voltage (V); V_{REF} is the reference voltage (0.85 V in TPS5110). The value for R1 is set as a part of the compensation circuit and the value of R2 may be calculated to achieve the desired output voltage. In the EVM design, the value of R1 was determined as R01A = R01B = 10 kΩ for V_{O1}, and R10 = 6.8 kΩ and R11 = 820 Ω for V_{O2} considering stability. For V_{O1}:

$$R03 = \frac{20 \text{ k}\Omega \times 0.85}{1.8 - 0.85} = 17.89 \text{ k}\Omega$$

Use 18 kΩ.

For V_{O2}:

$$R09 = \frac{(6.8 \text{ k}\Omega + 820) \times 0.85}{1.5 - 0.85} = 9.96 \text{ k}\Omega$$

Use 10 kΩ.

The values of R01A, R01B, R10 and R11 are chosen so that the calculated values of R03 and R09 are those of standard value resistor and the V_O setpoint maintains the highest precision. This can be best accomplished by combining two resistor values. If a standard value resistor can not be applied such as R10 and R11, use a value for R10 that is just slightly less than the desired total. A small value resistor in the range of tens or hundreds of ohms for R11 can then be added to generate the desired final value.

APPLICATION INFORMATION

output inductor selection

The required value for the output-filter inductor can be calculated by using the equation:

$$L_{OUT} = \frac{(V_{IN} - V_O)}{k \times I_{OUT}} \times \frac{V_O}{V_{IN}} \times \frac{1}{f_S}$$

Where L_{OUT} is output filter inductor value (H), V_{IN} is the input voltage (V), I_{OUT} is the maximum output current (A), f_S is the switching frequency (Hz). Constant value k , a ratio of ripple current to output current, is typically in the range 0.2 to 0.3. For V_{O1} , the calculation for the maximum input voltage of 20 V, yields a value for L_{O1} of 3.03 μ H, and for minimum input voltage of 8 V, 2.58 μ H. For the EVM, a value of 2.8 μ H is used for L_{O1} .

output inductor ripple current

The output-inductor current can affect not only the efficiency, but also the output voltage ripple. The equation is exhibited below:

$$I_{RIPPLE} = \frac{V_{IN} - V_O - I_O \times (R_{DS(on)} + R_L)}{L_{OUT}} \times \frac{V_O}{V_{IN}} \times \frac{1}{f_S}$$

where I_{RIPPLE} is the peak-to-peak ripple current (A) through the inductor; I_O is the output current; $R_{DS(on)}$ is the on-time resistance of MOSFET (Ω); R_L is the inductor dc resistance (Ω). From the equation, it can be seen that the current ripple can be adjusted by changing the output inductor value. For the EVM design, the worst-case output ripple occurs with $V_{IN} = 20$ V:

Example: $V_{IN} = 20$ V; $V_O = 1.8$ V; $I_O = 6$ A; $R_{DS(on)} = 25$ m Ω ; $R_L = 10$ m Ω ; $f_S = 300$ kHz; $L_{OUT} = 2.8$ μ H.

Then, the ripple current $I_{RIPPLE} = 1.93$ A

output capacitor selection (SBRC)

Selection of the output capacitor is basically dependent on the amount of peak-to-peak ripple voltage allowed on the output and the ability of the capacitor to dissipate the RMS ripple current. Assuming that the ESR of the output filter sees the entire inductor-ripple current then:

$$V_{PP} = I_{RIPPLE} \times R_{ESR}$$

And a suitable capacitor must be chosen so that the peak-to-peak output ripple is within the limits allowable for the application.

APPLICATION INFORMATION
output capacitor RMS current (SBRC)

Assuming the inductor-ripple current totally goes through the output capacitor to ground, the RMS current in the output capacitor can be calculated as:

$$I_{O(rms)} = \frac{I_{RIPPLE}}{\sqrt{12}}$$

where $I_{O(rms)}$ is maximum RMS current in the output capacitor (A); I_{RIPPLE} is the peak-to-peak inductor-ripple current (A).

Example: $I_{RIPPLE} = 1.93$ A, therefore, $I_{O(rms)} = 0.56$ A

input capacitor RMS current (SBRC)

Assuming the input current totally goes into the input capacitor to the power ground, the RMS current in the input capacitor can be calculated as:

$$I_{i(rms)} = \sqrt{I_O^2 \times D \times (1 - D) + \frac{1}{12} D \times I_{RIPPLE}^2}$$

where $I_{i(rms)}$ is the input RMS current in the input capacitor (A); I_O is the output current (A); I_{RIPPLE} is the peak-to-peak output inductor-ripple current; D is the duty cycle and defined as V_O/V_I in this case. From the equation, it can be seen that the highest input RMS current usually occurs at the lowest input voltage, so it is the worst case design for input capacitor ripple current.

Example: $I_O = 6$ A; $D = 22.5\%$; $I_{RIPPLE} = 1.6$ A then, $I_{i(rms)} = 2.5$ A

The input capacitors must be chosen so that together they can safely handle the input-ripple current. Depending on the input filtering and the dc input voltage source, not all the ripple current flows through the input capacitors, but some may be present on the input leads to the EVM.

soft start

The soft-start timing can be adjusted by selecting the soft-start capacitor value. The equation is;

$$C_{SOFT} = 2.3 \times 10^{-6} \times \frac{T_{SOFT}}{0.85}$$

where C_{SOFT} is the soft-start capacitor (μ F) (C04 in EVM design); T_{SOFT} is the start-up time (s).

Example: $T_{SOFT} = 5$ ms, therefore, $C_{SOFT} = 0.0135$ μ F.

APPLICATION INFORMATION

current protection (SBRC)

The current limit in TPS5110 is set using an internal current source and an external resistor (R13). The current limit protection circuit compares the drain-to-source voltage of the high-side and low-side drivers with respect to the set-point voltage. If the voltage up exceeds the limit during high-side conduction, the current-limit circuit terminates the high-side driver pulse. If the set point voltage is exceeded during low-side conduction, the low-side pulse is extended through the next cycle. Together this action has the effect of decreasing the output voltage until the under voltage protection circuit is activated and the fault latch is set and both the high and low-side MOSFET drivers are shut off. The equation below should be used for calculating the external resistor value for current protection set point:

$$R_{CL} = \frac{R_{DS(on)} \times \left(I_{TRIP} + \frac{I_{RIPPLE}}{2} \right)}{13 \times 10^{-6}}$$

where R_{CL} is the external current limit resistor (R13); $R_{DS(on)}$ is the low-side MOSFET(Q02) on-time resistance. I_{TRIP} is the required current limit.

Example: $R_{DS(on)} = 25 \text{ m}\Omega$, $I_{TRIP} = 6 \text{ A}$, $I_{RIPPLE} = 1.93 \text{ A}$, therefore, $R_{CL} = 13.4 \text{ k}\Omega$.

It should be noted that $R_{DS(on)}$ of a FET is highly dependent on temperature, so to insure full output at maximum operating temperature, the value of $R_{DS(on)}$ in the above equation should be adjusted. For maximum stability, it is recommended that the high-side MOSFET(s) has same, or slightly higher $R_{DS(on)}$ than the low-side MOSFET(s). If the low-side MOSFET(s) has a higher $R_{DS(on)}$, in certain low duty cycle applications it may be possible for the device to regulate at an output current higher than that set by the above equation by increasing the high side conduction time to compensate for the missed conduction cycle caused by the extension of the previous low-side pulse.

timer latch

The TPS5110 includes fault latch function with a user adjustable timer to latch the MOSFET drivers in case of a fault condition. When either the OVP or UVP comparator detect a fault condition, the timer starts to charge FLT capacitor (C07), which is connected with FLT pin 10. The circuit is designed so that for any value of FLT capacitor, the under-voltage latch time $t_{(uvplatch)}$ is about 50 times larger than the over-voltage latch time $t_{(ovplatch)}$. The equations needed to calculate the required value of the FLT capacitor for the desired over and under-voltage latch delay times are:

$$C_{LAT} = 2.3 \times 10^{-6} \times \frac{t_{(uvplatch)}}{1.185} \quad \text{and} \quad C_{LAT} = 125 \times 10^{-6} \times \frac{t_{(ovplatch)}}{1.185}$$

where C_{LAT} is the external capacitor, $t_{(uvplatch)}$ is the time from UVP detection to latch. $t_{(ovplatch)}$ is the time from OVP detection to latch.

For the EVM, $t_{(uvplatch)} = 5 \text{ ms}$ and $t_{(ovplatch)} = 0.1 \text{ ms}$, so $C_{LAT} = 0.01 \text{ }\mu\text{F}$

If the voltage on the FLT pin reaches 1.185 V, the fault latch is set, and the MOSFET drivers are set as follows:

under-voltage protection

The under-voltage comparator circuit continually monitors the voltage at the INV and INV_LDO pins. If the voltage at either pin falls below 65% of the 0.85-V reference, the timer begins to charge the FLT capacitor. If the fault condition persists beyond the time $t_{(uvplatch)}$, the fault latch is set and both the high side and low-side drivers, and LDO regulator drivers are forced OFF.

APPLICATION INFORMATION

short circuit protection

The short circuit protection circuitry uses the UVP circuit to latch the MOSFET drivers. When the current-limit circuit limits the output current, then the output voltage goes below the target-output voltage and UVP comparator detects a fault condition as described above.

over voltage protection

The over-voltage comparator circuit continually monitors the voltage at the INV and INV_LDO pins. If the voltage at either pin rises above 112% of the 0.85-V reference, the timer begins to charge the FLT capacitor. If the fault condition persists beyond the time $t_{(ovplatch)}$, the fault latch is set and the high-side drivers are forced OFF, while the low-side drivers are forced ON, and LDO regulator drivers are forced OFF.

CAUTION: Do not set the FLT pin to a lower voltage (or GND) while the device is timing out an OVP or UVP event. If the FLT pin is manually set to a lower voltage during this time, output overshoot may occur. The TPS5110 must be reset by grounding STBY and STBY_LDO, or dropping down REG5V_IN.

disablement of the protection function

If it is necessary to inhibit the protection functions of the TPS5110 for troubleshooting or other purposes, the OCP, OVP and UVP circuits may be disabled.

- OCP(SBRC): Remove the current-limit resistors R13 to disable the current limit function.
- OCP(LDO): Short-circuit R12 to disable the current limit function.
- OVP, UVP: Grounding the FLT pin can disable OVP and UVP.

output capacitor selection for LDO

To keep stable operation of the LDO, capacitance of more than 33 μ F and R_{ESR} of more than 30 m Ω are recommended for the output capacitor.

power MOSFET selection for LDO

Also, to keep stable operation of the LDO, lower input capacitance is recommended for the external power MOSFET. However, too small input capacitance may lead the feedback loop into unstable region. In such a case, the gate resistor of several hundred ohms keeps the LDO operation in the stable state.

current protection for LDO

If excess output current flows through sense resistor (R12) and the voltage drop exceeds 50 mV, the output voltage is reduced to approximately 22% of the nominal value, thus activates UVP to start the FLT latch timer.

When the set current is 4 A, the value of R12 is 12.5 m Ω .

APPLICATION INFORMATION

layout guidelines

Good power supply results only occur when care is given to proper design and layout. Layout affects noise pickup and generation and can cause a good design to perform with less than expected results. With a range of currents from milli-amps to tens of amps, good power supply layout is much more difficult than most general PCB designs. The general design should proceed from the switching node to the output, then back to the driver section and, finally, parallel the low-level components. Below are specific points to consider before the layout of a TPS5110 design begins.

- A four-layer PCB design is recommended for design using the TPS5110. For the EVM design, the top layer contains the interconnection to the TPS5110, plus some additional signal traces. Layer 2 is fully devoted to the DRVGND plane. Layer 3 mainly has wide VIN and V_{O1} pattern. The bottom layer is almost devoted to other GND plane including ANAGND, and the rest is to wide signal trace for V_{O2}.
- All sensitive analog components such as INV, REF, CT, GND, FLT and SOFTSTART should be reference to ANAGND.
- Ideally, all of the area directly under the TPS5110 chip should also be ANAGND.
- ANAGND and DRVGND should be isolated as much as possible, with a single point connection between them.

Figure 18. Four-Layer PCB Diagram

APPLICATION INFORMATION

low-side MOSFET(s)

- The source of low-side MOSFET(s) should be referenced to DRVGND, otherwise ANAGND is subject to the noise of the outputs.
- DRVGND should be connected to the main ground plane close to the source of the low-side FET.
- OUTGND should be placed close to the source of low-side MOSFET(s).
- The Schottky diode anode, the returns for the high-frequency bypass capacitor for the MOSFETs, and the source of the low-side MOSFET(s) traces should be routed as close together as possible.

Figure 19. Low-Side MOSFETs Diagram

APPLICATION INFORMATION

connections

- Connections from the drivers to the gate of the power MOSFETs should be as short and wide as possible to reduce stray inductance. This becomes more critical if external gate resistors are not being used. In addition, as for the current limit noise issue, use of a gate resistor on the high-side MOSFET(s) considerably reduce the noise at the LL node, improving the performance of the current limit function.
- The connection from LL to the power MOSFETs should be as short and wide as possible.

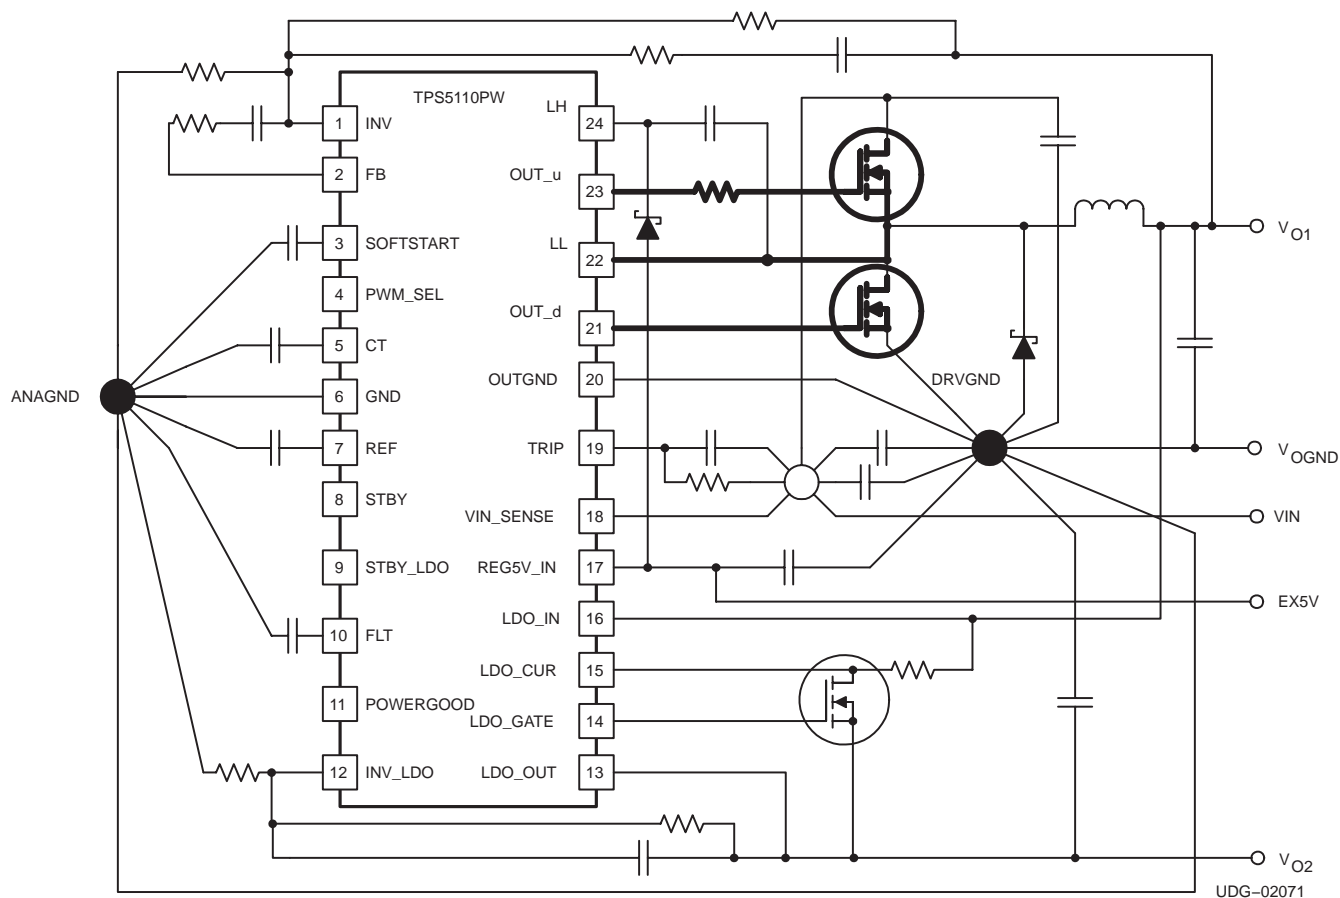

Figure 20. Connections From the Drivers to the Gate Diagram

APPLICATION INFORMATION

bypass capacitor

- The bypass capacitor for VIN_SENSE should be placed close to the TPS5110.
- The bulk-storage capacitors across VIN should be placed close to the power MOSFETs. High-frequency bypass capacitors should be placed in parallel with the bulk capacitors and connected close to the drain of the high-side MOSFET(s) and to the source of the low-side MOSFET(s).
- For aligning phase between the drain of high-side MOSFET(s) and the TRIP pin, and for noise reduction, a 0.1- μ F capacitor should be placed in parallel with the trip resistor.

Figure 21. Bypass Capacitor Diagram

APPLICATION INFORMATION

bootstrap capacitor

- The bootstrap capacitor (connected from LH to LL) should be placed close to the TPS5110.
- LH and LL should be routed close to each other to minimize differential-mode noise coupling to these traces.
- LH and LL should not be routed near the control pin area (ex. INV, FB, REF, etc.).

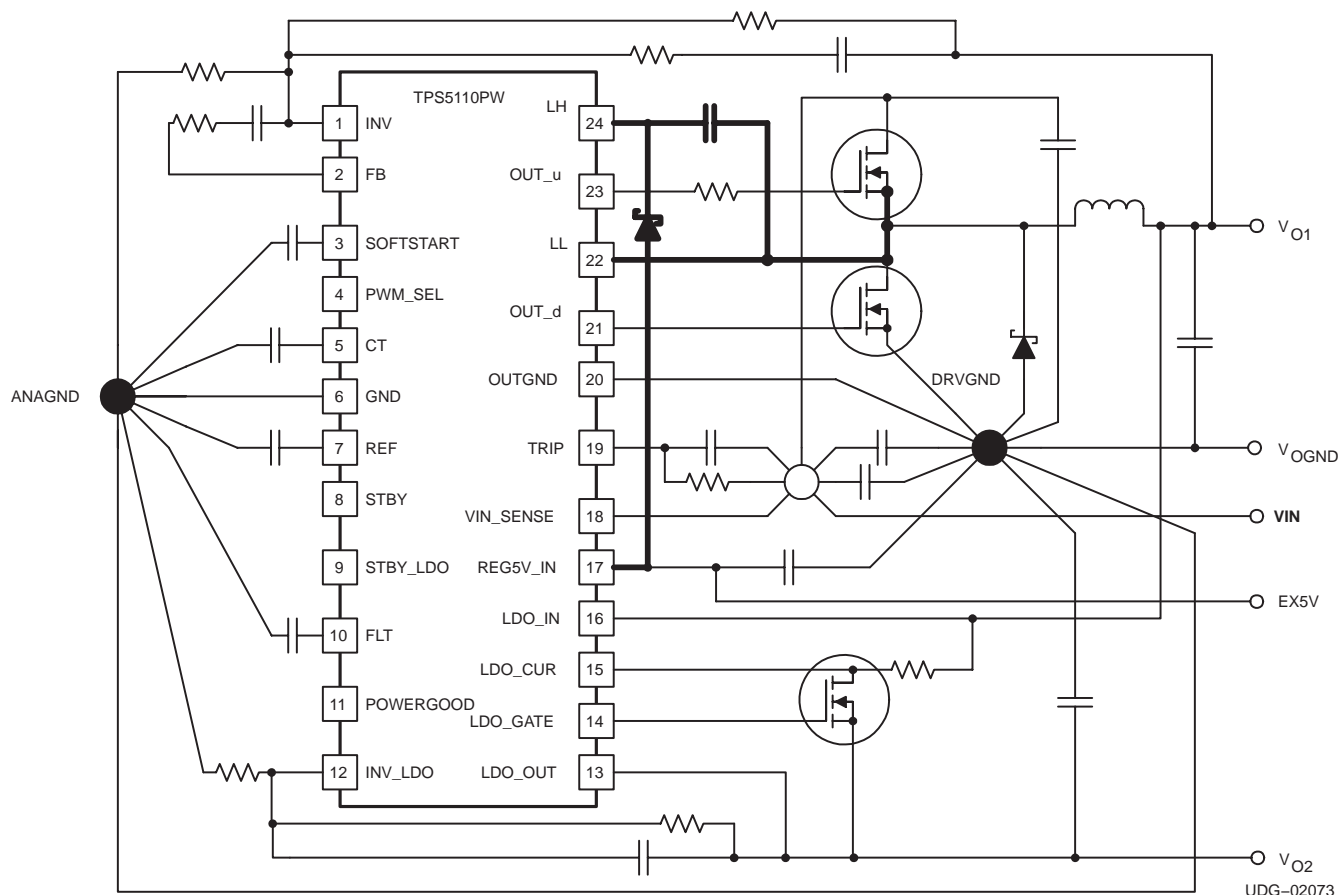

Figure 22. Bootstrap Capacitor Diagram

APPLICATION INFORMATION

output voltage

- The output voltage sensing trace should be isolated by either ground plane.
- The output voltage sensing trace should not be placed under the inductors on same layer.
- The feedback components should be isolated from output components, such as, MOSFETs, inductors, and output capacitors. Otherwise the feedback signal line is susceptible to output noise.
- The resistors for set up output voltage should be referenced to ANAGND.
- The INV trace should be as short as possible.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
