## Adjustable step-down controller with synchronous rectification dedicated to DDR memory

### Features

- Input voltage range from 1.8 V to 14 V
- Supply voltage range from 4.5 V to 14 V
- Adjustable output voltage down to 0.6 V with  $\pm 0.8\%$  Accuracy over line voltage and temperature (0 °C~125 °C)
- Fixed frequency voltage mode control
- $T_{ON}$  lower than 100 ns
- 0 % to 100 % duty cycle
- $V_{DDR}$  input sense
- Regulates  $V_{TT}$  and  $V_{TTREF}$  within 1 % of  $V_{DDQ}$
- Soft-start and inhibit
- High current embedded drivers
- Predictive anti-cross conduction control
- Programmable high-side and low-side  $R_{DS(on)}$  sense over-current-protection
- Selectable switching frequency 250 kHz / 500 kHz
- Power good output
- Sink/source capability for DDR memory and termination supply
- Over-voltage protection
- Thermal shutdown
- Package: HTSSOP16

### Applications

- High performance / high density DC-DC modules
- Low voltage distributed DC-DC
- niPoL converters
- DDR memory supply
- DDR termination supply
- Graphic cards

# 1 Summary description

The controller is an integrated circuit realized in BCD5 (BiCMOS-DMOS, version 5) fabrication that provides complete control logic and protection for high performance step-down DC-DC and niPoL converters.

It is designed to drive N-channel MOSFETs in a synchronous rectified buck topology. The output voltage of the converter can be precisely regulated down to 600 mV with a maximum tolerance of  $\pm 0.8\%$ . If an external reference is used, it will be transferred divided by 2 to the N.I. input of the error-amplifier, in accordance to the DDR memory specifications.

An internal resistor divider and a voltage buffer allow to achieve an accuracy of 1 % on both  $V_t$  and  $V_{tref}$ . It's possible to provide an external reference from 0V to 2.5 V in order to meet the specification for DDRI and DDRII. The input voltage can range from 1.8 V to 14 V, while the supply voltage can range from 4.5 V to 14 V. High peak current gate drivers provide for fast switching to the external power section, and the output current can be in excess of 20 A.

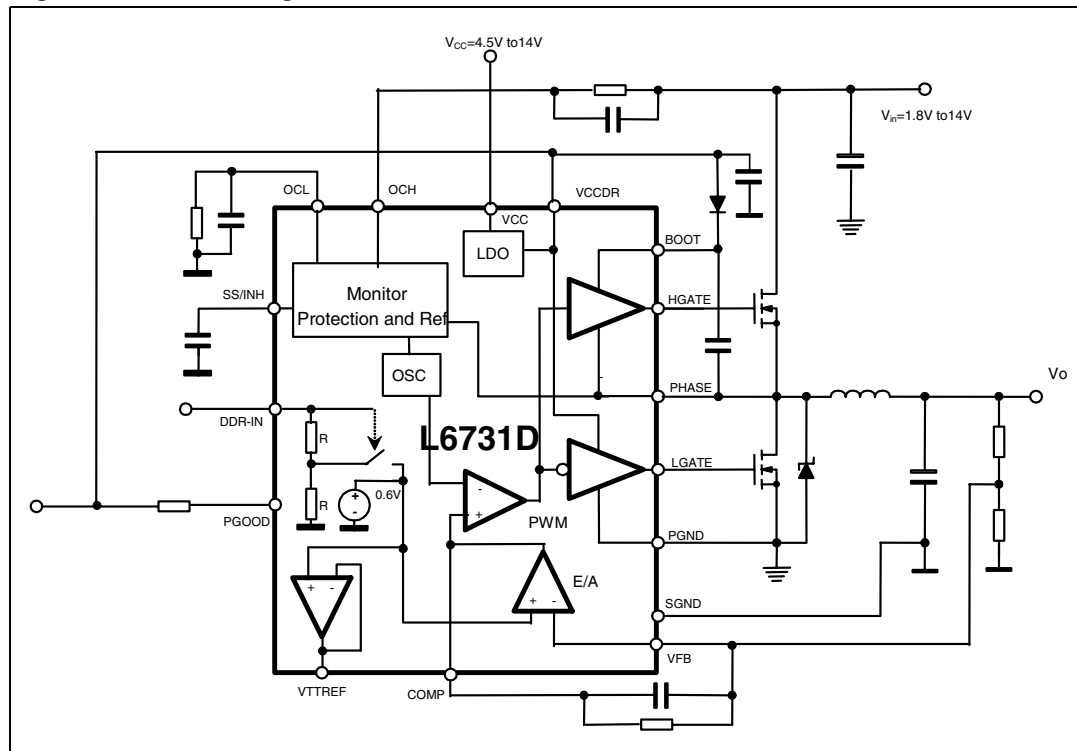

The PWM duty cycle can range from 0 % to 100 % with a minimum on-time ( $T_{ON, MIN}$ ) lower than 100 ns making possible conversions with very low duty cycle at high switching frequency. The device provides voltage-mode control that includes a selectable frequency oscillator (250 kHz or 500 kHz).

The error amplifier features a 10 MHz gain-bandwidth-product and 5 V/ $\mu$ s slew-rate that permits to realize high converter bandwidth for fast transient response. The device monitors the current by using the  $R_{DS(on)}$  of both the high-side and low-side MOSFET(s), eliminating the need for a current sensing resistor and guaranteeing an effective over-current-protection in all the application conditions.

When necessary, two different current limit protections can be externally set through two external resistors. During the soft-start phase a constant current protection is provided while after the soft-start the device enters in hiccup mode in case of over-current. The converter can always sink current. Other features are power good, not latched over-voltage-protection, feed-back disconnection and thermal shutdown. The HTSSOP16 package allows the realization of really compact DC/DC converters.

## 2 Electrical data

### 2.1 Maximum rating

**Table 2. Absolute maximum ratings**

Symbol	Parameter	Value	Unit
$V_{CC}$	$V_{CC}$ to GND and PGND, OCH, PGOOD	-0.3 to 18	V
$V_{BOOT}$ - $V_{PHASE}$	Boot voltage	0 to 6	V
$V_{HGATE}$ - $V_{PHASE}$		0 to $V_{BOOT} - V_{PHASE}$	V
$V_{BOOT}$	BOOT	-0.3 to 24	V
$V_{PHASE}$	PHASE	-1 to 18	V
	PHASE spike, transient < 50 ns ( $F_{SW} = 500$ kHz)	-3	
		+24	
	SS, FB, DDR-IN, SYNC, VTTREF, OCL, LGATE, COMP, $V_{CCDR}$	-0.3 to 6	V
OCH pin	Maximum withstanding voltage range test condition: CDF-AEC-Q100-002 "human body model" acceptance criteria: "normal performance"	±1500	V
PGOOD pin		±1000	
Other pins		±2000	

### 2.2 Thermal data

**Table 3. Thermal data**

Symbol	Description	Value	Unit
$R_{thJA}^{(1)}$	Thermal resistance junction to ambient	50	°C/W
$T_{STG}$	Storage temperature range	-40 to 150	°C
$T_J$	Junction operating temperature range	-40 to 125	°C
$T_A$	Ambient operating temperature range	-40 to +85	°C

1. Package mounted on demonstration board

### 3 Pin connections and functions

Figure 2. Pin connection (top view)

Table 4. Pin functions

Pin n.	Name	Function
1	PGOOD	This pin is an open collector output and it is pulled low if the output voltage is not within the specified thresholds (90 %-110 %). If not used it may be left floating. Pull-up this pin to V <sub>CDDR</sub> with a 10 K resistor to obtain a logical signal.
2	V <sub>TTREF</sub>	This pin is connected to the output of an internal buffer that provides ½ of DDR-IN. This pin can be connected to the V <sub>TTREF</sub> input of the DDR memory itself. Filter to GND with 10 nF capacitor.
3	SGND	All the internal references are referred to this pin.
4	FB	This pin is connected to the error amplifier inverting input. Connect it to V <sub>OUT</sub> through the compensation network. This pin is also used to sense the output voltage in order to manage the over voltage conditions and the PGood signal.
5	COMP	This pin is connected to the error amplifier output and is used to compensate the voltage control feedback loop.
6	SS/INH	The soft-start time is programmed connecting an external capacitor from this pin and GND. The internal current generator forces a current of 10 µA through the capacitor. When the voltage at this pin is lower than 0.5 V the device is disabled.
7	DDR-IN	By setting the voltage at this pin is possible to select the internal/external reference and the switching frequency: V <sub>EAREF</sub> 0-80 % of V <sub>CDDR</sub> -> External reference/F <sub>SW</sub> = 250 kHz V <sub>EAREF</sub> = 80 %-95 % of V <sub>CDDR</sub> -> V <sub>REF</sub> = 0.6 V/F <sub>SW</sub> = 500 kHz V <sub>EAREF</sub> = 95 %-100 % of V <sub>CDDR</sub> -> V <sub>REF</sub> = 0.6 V/F <sub>SW</sub> = 250 kHz An internal clamp limits the maximum V <sub>EAREF</sub> at 2.5 V (typ.). The device captures the analog value present at this pin at the start-up when V <sub>CC</sub> meets the UVLO threshold.

Table 4. Pin functions (continued)

Pin n.	Name	Function
8	OCL	<p>A resistor connected from this pin to ground sets the valley- current-limit. The valley current is sensed through the low-side MOSFET(s). The internal current generator sources a current of 100 <math>\mu</math>A (<math>I_{OCL}</math>) from this pin to ground through the external resistor (<math>R_{OCL}</math>). The over-current threshold is given by the following equation:</p> $I_{VALLEY} = \frac{I_{OCL} \cdot R_{OCL}}{2 \cdot R_{DSONLS}}$ <p>Connecting a capacitor from this pin to GND helps in reducing the noise injected from <math>V_{CC}</math> to the device, but can be a low impedance path for the high-frequency noise related to the GND. Connect a capacitor only to a "clean" GND.</p>
9	OCH	<p>A resistor connected from this pin and the high-side MOSFET(s) drain sets the peak-current-limit. The peak current is sensed through the high-side MOSFET(s). The internal 100 <math>\mu</math>A current generator (<math>I_{OCH}</math>) sinks a current from the drain through the external resistor (<math>R_{OCH}</math>). The over-current threshold is given by the following equation:</p> $I_{PEAK} = \frac{I_{OCH} \cdot R_{OCH}}{R_{DSONHS}}$
10	PHASE	This pin is connected to the source of the high-side MOSFET(s) and provides the return path for the high-side driver. This pin monitors the drop across both the upper and lower MOSFET(s) for the current limit together with OCH and OCL.
11	HGATE	This pin is connected to the high-side MOSFET(s) gate.
12	BOOT	Through this pin is supplied the high-side driver. Connect a capacitor from this pin to the PHASE pin and a diode from $V_{CCDR}$ to this pin (cathode versus BOOT).
13	PGND	This pin has to be connected closely to the low-side MOSFET(s) source in order to reduce the noise injection into the device.
14	LGATE	This pin is connected to the low-side MOSFET(s) gate.
15	$V_{CCDR}$	5 V internally regulated voltage. It is used to supply the internal drivers. Filter it to ground with at least 1 $\mu$ F ceramic cap.
16	$V_{CC}$	Supply voltage pin. The operative supply voltage range is from 4.5 V to 14 V.

## 4 Electrical characteristics

$V_{CC} = 12\text{ V}$ ,  $T_A = 25\text{ °C}$  unless otherwise specified.

## 5 Device description

### 5.1 Oscillator

The switching frequency can be fixed to two values: 250 kHz or 500 kHz by setting the proper voltage at the EAREF pin (see [Table 4](#). Pins function and section 4.3 Internal and external reference).

### 5.2 Internal LDO

An internal LDO supplies the internal circuitry of the device. The input of this stage is the  $V_{CC}$  pin and the output (5 V) is the  $V_{CCDR}$  pin ([Figure 3](#)).

**Figure 3. LDO block diagram**

The LDO can be by-passed, providing directly a 5 V voltage to  $V_{CCDR}$ . In this case  $V_{CC}$  and  $V_{CCDR}$  pins must be shorted together as shown in [Figure 4](#).  $V_{CCDR}$  pin must be filtered with at least 1  $\mu$ F capacitor to sustain the internal LDO during the recharge of the bootstrap capacitor.  $V_{CCDR}$  also represents a voltage reference for PGOOD pin (see [Table 4](#). Pins Function).

### 5.3 Bypassing the LDO to avoid the voltage drop with low Vcc

If  $V_{CC} \approx 5\text{ V}$  the internal LDO works in dropout with an output resistance of about  $1\ \Omega$ . The maximum LDO output current is about  $100\text{ mA}$  and so the output voltage drop is  $100\text{ mV}$ , to avoid this the LDO can be bypassed.

Figure 4. Bypassing the LDO

### 5.4 Internal and external references

It is possible to set the internal/external reference and the switching frequency by setting the proper voltage at the DDR-IN pin. The maximum value of the external reference is  $2.5\text{ V}$  (typ.):

- $V_{EAREF}$  from  $0\%$  to  $80\%$  of  $V_{CCDR}$  -> External reference/ $F_{SW} = 250\text{ kHz}$
- $V_{EAREF}$  from  $80\%$  to  $95\%$  of  $V_{CCDR}$  ->  $V_{REF} = 0.6\text{ V}/F_{SW} = 500\text{ kHz}$
- $V_{EAREF}$  from  $95\%$  to  $100\%$  of  $V_{CCDR}$  ->  $V_{REF} = 0.6\text{ V}/F_{SW} = 250\text{ kHz}$

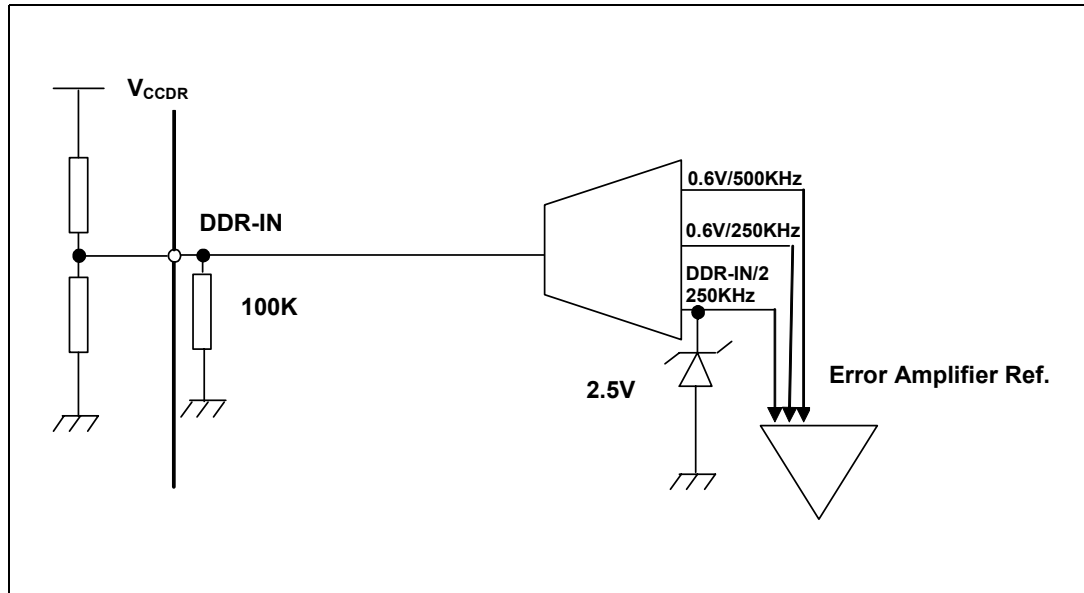

Providing an external reference from  $0\text{V}$  to  $450\text{mV}$  the output voltage will be regulated but some restrictions must be considered:

- $OV$  threshold saturates to a minimum value of  $300\text{ mV}$  ( $OV$  is tracking the reference; tracking small references will result in a narrow threshold reducing noise immunity)
- The under-voltage-protection doesn't work;
- The  $PGOOD$  signal remains low;

To set the resistor divider it must be considered that a  $100\text{ k}$  pull-down resistor is integrated into the device (see [Figure 5](#)). Finally it must be taken into account that the voltage at the DDR-IN pin is captured by the device at the start-up when  $V_{CC}$  is about  $4\text{ V}$ .

## 5.5 Error amplifier

Figure 5. Error amplifier reference

## 5.6 Soft-start

When both  $V_{CC}$  and  $V_{IN}$  are above their turn-ON thresholds ( $V_{IN}$  is monitored by the OCH pin) the start-up phase takes place. Otherwise the SS pin is internally shorted to GND. At start-up, a ramp is generated charging the external capacitor  $C_{SS}$  with an internal current generator. The initial value for this current is  $35 \mu A$  and charges the capacitor up to  $0.5V$ . After that it becomes  $10 \mu A$  until the final charge value of approximately  $4V$  (see [Figure 6](#)).

Figure 6. Device start-up: voltage at the SS pin

The reference of the error amplifier is clamped with this voltage ( $V_{SS}$ ) until it reaches the programmed value. The L6731D can always sink or source current. If an over current is detected during the soft-start phase, the device provides a constant-current-protection. In this way, in case of short soft-start time and/or small inductor value and/or high output capacitors value and so, in case of high ripple current during the soft-start, the converter can start in any case, limiting the current (see [5.8: Monitoring and protections](#)) but not entering in HICCUP mode. During normal operation, if any under-voltage is detected on one of the two supplies, the SS pin is internally shorted to GND and so the SS capacitor is rapidly discharged.

## 5.7 Driver section

The high-side and low-side drivers allow using different types of power MOSFETs (also multiple MOSFETs to reduce the  $R_{DS(on)}$ ), maintaining fast switching transitions. The low-side driver is supplied by  $V_{CCDR}$  while the high-side driver is supplied by the BOOT pin. A predictive dead time control avoids MOSFETs cross-conduction maintaining very short dead time duration in the range of 20 ns. The control monitors the phase node in order to sense the low-side body diode recirculation. If the phase node voltage is less than a certain threshold (-350 mV typ.) during the dead time, it will be reduced in the next PWM cycle. The predictive dead time control does not work when the high-side body diode is conducting because the phase node does not go negative. This situation happens when the converter is sinking current for example and, in this case, an adaptive dead time control operates.

## 5.8 Monitoring and protections

The output voltage is monitored by means of pin FB. If it is not within  $\pm 10\%$  (typ.) of the programmed value, the power good (PGOOD) output is forced low. The device provides over-voltage-protection: when the voltage sensed on FB pin reaches a value 20% (typ.) greater than the reference, the low-side driver is turned on as long as the over voltage is detected (see [Figure 7.](#)).

Figure 7. OVP

It must be taken into account that there is an electrical network between the output terminal and the FB pin and therefore the voltage at the pin is not a perfect replica of the output voltage. However due to the fact that the converter can sink current, in the most of cases the

low-side will turn-on before the output voltage exceeds the over-voltage threshold, because the error amplifier will throw off balance in advance. Even if the device doesn't report an over-voltage, the behavior is the same, because the low-side is turned-on immediately. The following figure shows the device behavior during an over-voltage event. The output voltage rises with a slope of 100 mV/μs, emulating in this way the breaking of the high-side MOSFET as an over-voltage cause.

**Figure 8. OVP: the low-side MOSFET is turned-on in advance**

The device realizes the over-current-protection (OCP) sensing the current both on the high-side MOSFET(s) and the low-side MOSFET(s) and so 2 current limit thresholds can be set (see OCH pin and OCL pin in [Table 4](#). Pins function):

- Peak current limit
- Valley current limit

The peak current protection is active when the high-side MOSFET(s) is turned on, after a masking time of about 100 ns. The valley-current-protection is enabled when the low-side MOSFET(s) is turned on after a masking time of about 400 ns. If, when the soft-start phase is completed, an over current event occurs during the on time (peak-current-protection) or during the off time (valley-current-protection) the device enters in HICCUP mode: the high-side and low-side MOSFET(s) are turned OFF, the soft-start capacitor is discharged with a constant current of 10 μA and when the voltage at the SS pin reaches 0.5 V the soft-start phase restarts. During the soft-start phase the OCP provides a constant-current-protection. If during the T<sub>ON</sub> the OCH comparator triggers an over current the high-side MOSFET(s) is immediately turned OFF (after the masking time and the internal delay) and returned on at the next PWM cycle. The limit of this protection is that the T<sub>ON</sub> can't be less than masking time plus propagation delay because during the masking time the peak-current-protection is disabled. In case of very hard short circuit, even with this short T<sub>ON</sub>, the current could escalate.

The valley-current-protection is very helpful in this case to limit the current. If during the off-time the OCL comparator triggers an over current, the high-side MOSFET(s) is not turned on until the current is over the valley-current-limit.

This implies that, if it is necessary, some pulses of the high-side MOSFET(s) will be skipped, guaranteeing a maximum current due to the following formula:

**Equation 1**

$$I_{MAX} = I_{VALLEY} + \frac{V_{in} - V_{out}}{L} \cdot T_{ON,MIN}$$

During soft-start the OC acts in constant current mode: a current control loop limits the value of the error amplifier output (comp), in order to avoid its saturation and thus recover faster when the output returns in regulation. *Figure 9.* shows the behavior of the device during an over current condition that persists also in the soft-start phase.

L6732 provides Under Voltage (UV) protection: when the voltage on FB pin falls below 80% of the reference, the IC will enter HICCUP mode.

Feedback disconnection is also provided by sourcing a 100 nA current from FB pin. if FB results being floating, the IC will detect and OV so latching its condition with low side MOSFET firmly ON.

**5.9 HICCUP mode during an OCP****Figure 9. Constant current and hiccup mode during an OCP****5.10 Thermal shutdown**

When the junction temperature reaches  $150\text{ °C} \pm 10\text{ °C}$  the device enters in thermal shutdown. Both MOSFETs are turned off and the soft-start capacitor is rapidly discharged with an internal switch. The device doesn't restart until the junction temperature goes down to  $120\text{ °C}$  and, in any case, until the voltage at the soft-start pin reaches 500 mV.

**5.11 Minimum on-time ( $T_{ON, MIN}$ )**

The device can manage minimum on-times lower than 100ns. This feature comes down from the control topology and from the particular over-current-protection system of the L6731D. In fact, in a voltage mode controller the current has not to be sensed to perform the regulation and, in the case of L6731D, neither for the over-current protection, given that

during the off-time the valley-current-protection can operate in every case. The first advantage related to this feature is the possibility to realize extremely low conversion ratios. *Figure 10.* shows a conversion from 14 V to 0.3 V at 500 kHz with a  $T_{ON}$  of about 50 ns.

**Figure 10. 14 V -> 0.3 V @ 500 kHz, 5 A**

The on-time is limited by the turn-on and turn-off times of the MOSFETs.

## 6 Application details

### 6.1 Inductor design

The inductance value is defined by a compromise between the transient response time, the efficiency, the cost and the size. The inductor has to be calculated to sustain the output and the input voltage variation to maintain the ripple current ( $\Delta I_L$ ) between 20 % and 30 % of the maximum output current. The inductance value can be calculated with the following relationship:

**Equation 2**

$$L \cong \frac{V_{in} - V_{out}}{F_{sw} \cdot \Delta I_L} \cdot \frac{V_{out}}{V_{in}}$$

Where  $F_{SW}$  is the switching frequency,  $V_{in}$  is the input voltage and  $V_{out}$  is the output voltage. Increasing the value of the inductance reduces the ripple current but, at the same time, increases the converter response time to a load transient. If the compensation network is well designed, during a load transient the device is able to set the duty cycle to 100 % or to 0 %. When one of these conditions is reached, the response time is limited by the time required to change the inductor current. During this time the output current is supplied by the output capacitors. Minimizing the response time can minimize the output capacitor size.

### 6.2 Output capacitors

The output capacitors are basic components for the fast transient response of the power supply. They depend on the output voltage ripple requirements, as well as any output voltage deviation requirement during a load transient. During a load transient, the output capacitors supply the current to the load or absorb the current stored in the inductor until the converter reacts. In fact, even if the controller recognizes immediately the load transient and sets the duty cycle at 100 % or 0 %, the current slope is limited by the inductor value. The output voltage has a first drop due to the current variation inside the capacitor (neglecting the effect of the ESL):

**Equation 3**

$$\Delta V_{out_{ESR}} = \Delta I_{out} \cdot ESR$$

Moreover, there is an additional drop due to the effective capacitor discharge or charge that is given by the following formulas:

**Equation 4**

$$\Delta V_{out_{COUT}} = \frac{\Delta I_{out}^2 \cdot L}{2 \cdot C_{out} \cdot (V_{in, \min} \cdot D_{\max} - V_{out})}$$

**Equation 5**

$$\Delta V_{out_{COUT}} = \frac{\Delta I_{out}^2 \cdot L}{2 \cdot C_{out} \cdot V_{out}}$$

Formula (4) is valid in case of positive load transient while the formula (5) is valid in case of negative load transient.  $D_{MAX}$  is the maximum duty cycle value that in the L6731D is 100%.

For a given inductor value, minimum input voltage, output voltage and maximum load transient, a maximum ESR and a minimum Cout value can be set. The ESR and Cout values also affect the static output voltage ripple. In the worst case the output voltage ripple can be calculated with the following formula:

**Equation 6**

$$\Delta V_{out} = \Delta I_L \cdot \left( ESR + \frac{1}{8 \cdot C_{out} \cdot F_{sw}} \right)$$

Usually the voltage drop due to the ESR is the biggest one while the drop due to the capacitor discharge is almost negligible.

### 6.3 Input capacitors

The input capacitors have to sustain the RMS current flowing through them, that is:

**Equation 7**

$$I_{rms} = I_{out} \cdot \sqrt{D \cdot (1 - D)}$$

Where D is the duty cycle. The equation reaches its maximum value,  $I_{OUT}/2$  with  $D = 0.5$ . The losses in worst case are:

**Equation 8**

$$P = ESR \cdot (0.5 \cdot I_{out})^2$$

### 6.4 Compensation network

The loop is based on a voltage mode control ([Figure 18](#)). The output voltage is regulated to the internal/external reference voltage and scaled by the external resistor divider. The error amplifier output  $V_{COMP}$  is then compared with the oscillator triangular wave to provide a pulse-width modulated (PWM) with an amplitude of  $V_{IN}$  at the PHASE node. This waveform is filtered by the output filter. The modulator transfer function is the small signal transfer function of  $V_{OUT}/V_{COMP}$ . This function has a double pole at frequency  $F_{LC}$  depending on the L- $C_{OUT}$  resonance and a zero at  $F_{ESR}$  depending on the output capacitor's ESR. The DC Gain of the modulator is simply the input voltage  $V_{IN}$  divided by the peak-to-peak oscillator voltage:  $V_{OSC}$ .

Equation 12

$$\omega_{P2} = \frac{1}{R_4 \cdot C_{20}}$$

Equation 13

$$\omega_{Z1} = \frac{1}{R_5 \cdot C_{19}}$$

Equation 14

$$\omega_{Z2} = \frac{1}{C_{20} \cdot (R_3 + R_4)}$$

- Compensation network design:
  - Put the gain  $R_5/R_3$  in order to obtain the desired converter bandwidth

Equation 15

$$\omega_C = \frac{R_5}{R_3} \cdot \frac{V_{in}}{\Delta V_{osc}} \cdot \omega_{LC}$$

- Place  $\omega_{Z1}$  before the output filter resonance  $\omega_{LC}$ ;
- Place  $\omega_{Z2}$  at the output filter resonance  $\omega_{LC}$ ;
- Place  $\omega_{P1}$  at the output capacitor ESR zero  $\omega_{ESR}$ ;
- Place  $\omega_{P2}$  at one half of the switching frequency;
- Check the loop gain considering the error amplifier open loop gain.

## 7 Package mechanical data

In order to meet environmental requirements, ST offers these devices in ECOPACK<sup>®</sup> packages. These packages have a lead-free second level interconnect. The category of second Level Interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark. ECOPACK specifications are available at: [www.st.com](http://www.st.com).
