

FAN5355 1A / 0.8A, 3MHz Digitally Programmable TinyBuck™ Regulator

Features

- 91% Efficiency at 3MHz
- 800mA or 1A Output Current⁽¹⁾
- 2.7V to 5.5V Input Voltage Range
- 6 or 7-bit V_{OUT} Programmable from 0.75 to 1.975V
- 3MHz Fixed-Frequency Operation
- Excellent Load and Line Transient Response
- Small Size, 1μH Inductor Solution
- ±2% PWM DC Voltage Accuracy
- 35ns Minimum On-Time
- High-Efficiency, Low-Ripple, Light-Load PFM
- Smooth Transition between PWM and PFM
- 37μA Operating PFM Quiescent Current
- Software Selectable 25kHz Minimum PFM Frequency Prevents Audible Noise in PFM Mode
- I²C™-Compatible Interface up to 3.4Mbps
- Pin-Selectable or I²C™ Programmable Output Voltage
- On-the-Fly External Clock Synchronization
- 10-lead MLP (3 x 3mm) or 12-bump CSP Packages

Applications

- SmartReflex™-Compliant Power Supply
- Split Supply DSPs and μP Solutions OMAP™, XSCALE™
- Cell Phones, Smart Phones, PDAs, Digital Cameras, and Portable Media Players
- Micro DC-DC Converter Modules
- Handset Graphic Processors (NVIDIA®, ATI)

I²C is a trademark of Philips Corporation.
SmartReflex and OMAP are trademarks of Texas Instruments.
XSCALE is a trademark of Intel Corporation.
NVIDIA is a registered trademark of NVIDIA Corporation.

Description

The FAN5355 device is a high-frequency, ultra-fast transient response, synchronous step-down DC-DC converter optimized for low-power applications using small, low-cost inductors and capacitors. The FAN5355 supports up to 800mA or 1A⁽¹⁾ load current.

The device is ideal for mobile phones and similar portable applications powered by a single-cell Lithium-Ion battery. With an output voltage range adjustable via I²C™ interface from 0.75V to 1.975V, the device supports low-voltage DSPs and processors, core power supplies in smart phones, PDAs, and handheld computers.

The FAN5355 operates at 3MHz (nominal) fixed switching frequency using either its internal oscillator or external SYNC frequency.

During light-load conditions, the regulator includes a PFM mode to enhance light-load efficiency. The regulator transitions smoothly between PWM and PFM modes with no glitches on V_{OUT}. Normal PFM (NPFM) mode offers the lowest quiescent current, at the expense of setpoint accuracy. Enhanced PFM (EPFM) mode features higher accuracy, as well as a 25kHz minimum PFM frequency, designed to prevent the regulator from operating in the audible range. In shutdown, the current consumption is reduced to less than 2μA, using software shutdown (EN = 1 with EN_DCDC = 0), and less than 200nA in hardware shutdown (EN = 0).

The serial interface is compatible with Fast/Standard and High-Speed mode I²C specifications, allowing transfers up to 3.4Mbps. This interface is used for dynamic voltage scaling with 12.5mV voltage steps, for reprogramming the mode of operation (PFM or Forced PWM), or to disable/enable the output voltage.

The chip's advanced protection features include short-circuit protection and current and temperature limits. During a sustained over-current event, the IC shuts down and restarts after a delay to reduce average power dissipation into a fault.

During start-up, the IC controls the output slew rate to minimize input current and output overshoot at the end of soft-start. The IC maintains a consistent soft-start ramp, regardless of output load during start-up.

The FAN5355 is available in 10-lead MLP (3x3mm) and 12-bump CSP packages.

Ordering Information

Order Number ⁽⁴⁾	Option	Slave Address LSB		V _{OUT} Programming			Power-up Defaults		Package ⁽⁴⁾ 
		A1	A0	DAC	MIN.	MAX.	VSEL0	VSEL1

FAN5355MP07X	07 ⁽¹⁾	1	1	7	0.7500 ⁽³⁾	1.9750	1.05	1.35	MLP-10, 3x3mm

Notes:

- Option 06 and 07 is rated for 1A output current. All other options are rated for 800mA output current.
- V_{OUT} is limited to the maximum voltage for all VSEL codes greater than the maximum V_{OUT} listed.
- V_{OUT} may be programmed down 100mV for option 07. Performance below 0.75V is not guaranteed.
-  All packages are “green” per JEDEC: J-STD-020B standard. The “X” designator specifies tape and reel packaging.

Typical Application

Figure 1. Typical Application

Component	Description	Vendor	Parameter	Min.	Typ.	Max.	Units
L1 (L _{OUT})	1μH nominal	Murata LQM31P or FDK MIPS2520	L ⁽⁵⁾	0.7	1.0	1.2	μH

C _{OUT}	0603 (1.6x0.8x0.8) 10μF X5R or better	Murata or equivalent GRM188R60G106ME47D	C ⁽⁶⁾	5.6	10.0	12.0	μF
C _{IN}	0603 (1.6x0.8x0.8) 4.7μF X5R or better	Murata or equivalent GRM188R60J475KE19D	C ⁽⁶⁾	3.0	4.7	5.6	μF

Table 1. Recommended External Components

Notes:

- Minimum L incorporates both tolerance, temperature, and partial saturation effects (L decreases with increasing current).
- Minimum C is a function of initial tolerance, maximum temperature, and the effective capacitance being reduced due to frequency, dielectric, and voltage bias effects.

Pin Configuration

Top View

Bottom View

Figure 2. WLCSP- 12, 2.23x1.46mm

Top View

Figure 3. MLP10, 3x3mm

Pin Definitions

Pin #		Name	Description
WLCSP	MLP		
A1, B1	9	PGND	Power GND. Power return for gate drive and power transistors. Connect to AGND on PCB. The connection from this pin to the bottom of C_{IN} should be as short as possible.
A2	10	SW	Switching Node. Connect to output inductor.
A3	1	PVIN	Power Input Voltage. Connect to input power source. The connection from this pin to C_{IN} should be as short as possible.
B2	N/A	SYNC	Sync. When toggling and SYNC_EN bit is HIGH, the regulator synchronizes to the frequency on this pin. In PWM mode, when this pin is statically LOW or statically HIGH, or when its frequency is outside of the specified capture range, the regulator's frequency is controlled by its internal 3MHz clock.
B3	2	AVIN	Analog Input Voltage. Connect to input power source as close as possible to the input bypass capacitor.
C1	8, PAD	AGND	Analog GND. This is the signal ground reference for the IC. All voltage levels are measured with respect to this pin.
C2	7	EN	Enable. When this pin is HIGH, the circuit is enabled. When LOW, quiescent current is minimized. This pin should not be left floating.
C3	3	SDA	SDA. I ² C interface serial data.
D1	6	VOOUT	Output Voltage Monitor. Tie this pin to the output voltage. This is a signal input pin to the control circuit and does not carry DC current.
D2	5	VSEL	Voltage Select. When HIGH, V_{OUT} is set by VSEL1. When LOW, V_{OUT} is set by VSEL0. This behavior can be overridden through I ² C register settings. This pin should not be left floating.
D3	4	SCL	SCL. I ² C interface serial clock.

Note:

- All logic inputs (SDA, SCL, SYNC, EN, and VSEL) are high impedance and should not be left floating. For minimum quiescent power consumption, tie unused logic inputs to AVIN or AGND. If I²C control is unused, tie SDA and SCL to AVIN.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter	Min.	Max.	Units
V _{CC}	AVIN, SW, PVIN Pins	-0.3	6.5	V
	Other Pins	-0.3	AVIN + 0.3 ⁽⁸⁾	V
ESD	Electrostatic Discharge Protection Level	Human Body Model per JESD22-A114		KV
		Charged Device Model per JESD22-C101		KV
T _J	Junction Temperature	-40	+150	°C
T _{STG}	Storage Temperature	-65	+150	°C
T _L	Lead Soldering Temperature, 10 Seconds		+260	°C

Note:

8. Lesser of 6.5V or V_{CC}+0.3V.

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to absolute maximum ratings.

Symbol	Parameter	Min.	Max.	Units
V _{IN}	Supply Voltage	2.7	5.5	V
f	Frequency Range	2.7	3.3	MHz
V _{SW}	SDA and SCL Voltage Swing ⁽⁹⁾		2.5	V
T _A	Ambient Temperature	-40	+85	°C
T _J	Junction Temperature	-40	+125	°C

Note:

9. The I²C interface operates with t_{HD, DAT} = 0 as long as the pull-up voltage for SDA and SCL is less than 2.5V. If voltage swings greater than 2.5V are required (for example if the I²C bus is pulled up to V_{IN}), the minimum t_{HD, DAT} must be increased to 80ns. Most I²C masters change SDA near the midpoint between the falling and rising edges of SCL, which provides ample t_{HD, DAT}.

Dissipation Ratings⁽¹⁰⁾

Package	R θ_{JA} ⁽¹¹⁾	Power Rating at T _A ≤ 25°C	Derating Factor > T _A = 25°C
Molded Leadless Package (MLP)	49°C/W	2050mW	21mW/°C
Wafer-Level Chip-Scale Package (WLCSP)	110°C/W	900mW	9mW/°C

Notes:

10. Maximum power dissipation is a function of T_{J(max)}, θ_{JA} , and T_A. The maximum allowable power dissipation at any allowable ambient temperature is P_D = [T_{J(max)} - T_A] / θ_{JA} .
11. This thermal data is measured with high-K board (four-layer board according to JESD51-7 JEDEC standard).

Electrical Specifications

$V_{IN} = 3.6V$, $EN = V_{IN}$, $VSEL = V_{IN}$, $SYNC = GND$, $VSEL0(6)$ bit = 1, $CONTROL2[4:3] = 00$. $T_A = -40^{\circ}C$ to $+85^{\circ}C$, unless otherwise noted. Typical values are at $T_A = 25^{\circ}C$. Circuit and components according to Figure 1.

Circuit Description

Overview

The FAN5355 is a synchronous buck regulator that typically operates at 3MHz with moderate to heavy load currents. At light load currents, the converter operates in power-saving PFM mode. The regulator automatically transitions between fixed-frequency PWM and variable-frequency PFM mode to maintain the highest possible efficiency over the full range of load current.

The FAN5355 uses a very fast non-linear control architecture to achieve excellent transient response with minimum-sized external components.

The FAN5355 integrates an I²C-compatible interface, allowing transfers up to 3.4Mbps. This communication interface can be used to:

1. Dynamically re-program the output voltage in 12.5mV increments.
2. Reprogram the mode of operation to enable or disable PFM mode.
3. Control voltage transition slew rate.
4. Control the frequency of operation by synchronizing to an external clock.
5. Enable / disable the regulator.

For more details, refer to the I²C Interface and Register Description sections.

Output Voltage Programming

Option	V _{OUT} Equation	
00, 02, 03	$V_{OUT} = 0.75 + N_{VSEL} \cdot 12.5mV$	(1)
07	$V_{OUT} = 0.100 + N_{VSEL} \cdot 25mV$ for $N_{VSEL} = 0$ to 23 $V_{OUT} = 0.675 + (N_{VSEL} - 23) \cdot 12.5mV$ for $N_{VSEL} > 23$	(2)
06	$V_{OUT} = 1.1875 + N_{VSEL} \cdot 12.5mV$	(3)

where N_{VSEL} is the decimal value of the setting of the VSEL register that controls V_{OUT} .

Note:

13. Option 02 maximum voltage is 1.4375V (see Table 3).

Power-up, EN, and Soft-start

All internal circuits remain de-biased and the IC is in a very low quiescent current state until the following are true:

1. V_{IN} is above its rising UVLO threshold, and
2. EN is HIGH.

At that point, the IC begins a soft-start cycle, its I²C interface is enabled, and its registers loaded with their default values.

During the initial soft-start, V_{OUT} ramps linearly to the setpoint programmed in the VSEL register selected by the VSEL pin. The soft start features a fixed output voltage slew rate of 18.75V/ms, and achieves regulation approximately 90 μ s after EN rises. PFM mode is enabled during soft-start until the output is in regulation, regardless of the MODE bit settings. This allows the regulator to start into a partially charged output without discharging it; in other words, the regulator does not allow current to flow from the load back to the battery.

As soon as the output has reached its setpoint, the control forces PWM mode for about 85 μ s to allow all internal control circuits to calibrate.

Symbol	Description	Value (μ s)	
t_{SSDLY}	Time from EN to start of soft-start ramp	25	
t_{REG}	V_{OUT} ramp start to regulation	Opt 06	$16 + (VSEL - 0.7) \times 53$
		Others	$(VSEL - 0.1) \times 53$
t_{POK}	PWROK (CONTROL2[5]) rising from t_{REG}	11	
t_{CAL}	Regulator stays in PWM mode during this time	10

Table 4. VSEL vs. VOUT for Option 07

Software Enable

The EN_DCDC bit, VSELx[7] can be used to enable the regulator in conjunction with the EN pin. Setting EN_DCDC with EN HIGH begins the soft-start sequence described above.

EN_DCDC Bit	EN Pin	I ² C	REGULATOR
0	0	OFF	OFF
1	1	ON	ON
1	0	OFF	OFF
0	1	ON	OFF

Table 5. EN_DCDC Behavior

Light-Load (PFM) Operation

The FAN5355 offers both a Normal PFM (NPFM) and Enhanced PFM (EPFM) mode. NPFM is normally used when the load current is very low and when quiescent current must be minimized. EPFM provides more accurate DC regulation and limits the minimum frequency to 25kHz typical to prevent operation in the audio band.

V_{OUT} ripple is identical in both modes (less than 20mV), and both modes feature very fast response to load transients.

The FAN5355 incorporates a single-pulse, light-load modulation that ensures:

- Smooth transitions between PFM and PWM modes
- Minimum frequency, of 25kHz typical, to avoid audible noise (EPFM only)
- Single-pulse operation for low ripple
- Predictable PFM entry and exit currents.

PFM begins after the inductor current has become discontinuous, crossing zero during the PWM cycle in 32 consecutive cycles. PFM exit occurs when discontinuous current mode (DCM) operation cannot supply sufficient current to maintain regulation. During PFM mode, the inductor current ripple is about 40% higher than in PWM mode. The load current required to exit PFM mode is thereby about 20% higher than the load current required to enter PFM mode, providing sufficient hysteresis to prevent “mode chatter.”

While PWM ripple voltage is typically less than 4mV_{P-P}, PFM ripple voltage can be up to 30mV_{P-P} during very light load. To prevent significant undershoot when a load transient occurs, the initial DC setpoint for the regulator in PFM mode is set 10mV higher than in PWM mode. This offset decays to about 5mV after the regulator has been in PFM mode for ~100μs. The maximum instantaneous voltage in PFM is 30mV above the setpoint.

In Enhanced PFM (EPFM) mode, the regulator maintains a minimum frequency of 25kHz (typical) to prevent audible noise being generated by the external components. To achieve this, the regulator turns on the low-side MOSFET to

“create demand” for a pulse if no pulse had been required for 40μs. The minimum frequency limit circuit takes effect with load currents below about 3.5mA. Above that load point, the natural PFM period is less than 40μs. This circuit only activates when I_{LOAD} is greater than ~3.5mA. If the load remains above 3.5mA, there is no quiescent current penalty for EPFM mode and there is some accuracy advantage.

NPFM allows the switching frequency (f_{SW}) to go as low as required to support the load current. This achieves a lower quiescent current than EPFM, but sacrifices up to ±15mV of DC accuracy when compared to EPFM or PWM modes. As shown in Table 6, EPFM and NPFM modes have the same frequency when the load is above 4mA. If the load is above 4mA, EPFM is the preferred mode, since it has tighter DC regulation with the same efficiency.

EPFM can only be enabled by setting the MODE_CTRL bits to 11. In versions with MODE_CTRL disabled (see Table 12), the PFM mode is NPFM.

Mode	EPFM	NPFM
I _{QUIESCENT} typical at I _{LOAD} = 0	110μA	38μA
DC Accuracy	Better	Good
f _{SW} at I _{LOAD} = 0	25 kHz	to 0 Hz
f _{SW} at I _{LOAD} > 3.5mA	> 33 kHz	> 33 kHz

Table 6. PFM Modes Comparison

PFM mode can be disabled by writing to the mode control bits: CONTROL1[3:0] (see Table 12 for details).

Switching Frequency Control and Synchronization

The nominal internal oscillator frequency is 3MHz. The regulator runs at its internal clock frequency until these conditions are met:

1. EN_SYNC bit, CONTROL1[5], is set; and
2. A valid frequency appears on the SYNC pin.

CONTROL2		F _{SYNC} Valid		
PLL_MULT	f _{SYNC} Divider	Min.	Typ.	Max.
00	1	2.25	3.00	4.00
01	2	1.13	1.50	2.00
10	3	0.75	1.00	1.33
11	4	0.56	0.75	1.00

Table 7. SYNC Frequency Validation for f_{OSC(INTERNAL)}=3.0MHz

If the EN_SYNC is set and SYNC fails validation, the regulator continues to run at its internal oscillator frequency. The regulator is functional if f_{SYNC} is valid, as defined in Table 7, but its performance is compromised if f_{SYNC} is outside the f_{SYNC} window in the Electrical Specifications.

When CONTROL1[3:2] = 00 and the VSEL line is LOW, the converter operates according to the MODE0 bit, CONTROL1[0], with synchronization disabled regardless of the state of the EN_SYNC and HW_nSW bits.

Output Voltage Transitions

The IC regulates V_{OUT} to one of two setpoint voltages, as determined by the VSEL pin and the HW_nSW bit.

VSEL Pin	HW_nSW Bit	V_{OUT} Setpoint ⁽¹⁴⁾	PFM
0	1	VSEL0	Allowed
1	1	VSEL1	Per MODE1
x	0	VSEL1	Per MODE1

Table 8. V_{OUT} Setpoint and Mode Control MODE_CTRL, CONTROL1[3:2] = 00

Note:

14. Option 07 uses VSELx[6:0] to set V_{OUT} , while all other options use VSELx[5:0].

If HW_nSW = 0, V_{OUT} transitions are initiated through the following sequence:

1. Write the new setpoint in VSEL1.
2. Write desired transition rate in DEFSLEW, CONTROL2[2:0], and set the GO bit in CONTROL2[7].

If HW_nSW = 1, V_{OUT} transitions are initiated either by changing the state of the VSEL pin or by writing to the VSEL register selected by the VSEL pin.

Positive Transitions

When transitioning to a higher V_{OUT} , the regulator can perform the transition using multi-step or single-step mode.

Multi-step Mode:

The internal DAC is stepped at a rate defined by DEFSLEW, CONTROL2[2:0], ranging from 000 to 110. This mode minimizes the current required to charge C_{OUT} and thereby minimizes the current drain from the battery when transitioning. The PWROK bit, CONTROL2[5], remains LOW until about 1.5 μ s after the DAC completes its ramp.

Figure 36. Multi-step V_{OUT} Transition

Single-step Mode:

Used if DEFSLEW, CONTROL2[2:0] = 111. The internal DAC is immediately set to the higher voltage and the regulator performs the transition as quickly as its current limit circuit allows, while avoiding excessive overshoot.

Figure 37 shows single-step transition timing. $t_{V(L-H)}$ is the time it takes the regulator to settle to within 2% of the new

setpoint and is typically 7 μ s for a full-range transition (from 00000 to 11111 for 6-bit DAC options). The PWROK bit, CONTROL2[5], goes LOW until the transition is complete and V_{OUT} settled. This typically occurs ~2 μ s after $t_{V(L-H)}$.

It is good practice to reduce the load current before making positive VSEL transitions. This reduces the time required to make positive load transitions and avoids current-limit-induced overshoot.

Figure 37. Single-Step V_{OUT} Transition

All positive V_{OUT} transitions inhibit PFM until the transition is complete, which occurs at the end of $t_{POK(L-H)}$.

Negative Transitions

When moving from VSEL=1 to VSEL=0, the regulator enters PFM mode, regardless of the condition of the SYNC pin or MODE bits, and remains in PFM until the transition is completed. Reverse current through the inductor is blocked, and the PFM minimum frequency control inhibited, until the new setpoint is reached, at which time the regulator resumes control using the mode established by MODE_CTRL. The transition time from V_{HIGH} to V_{LOW} is controlled by the load current and output capacitance as:

$$t_{V(H-L)} = C_{OUT} \cdot \frac{V_{HIGH} - V_{LOW}}{I_{LOAD}} \quad (4)$$

Figure 38. Negative V_{OUT} Transition

Protection Features

Current Limit / Auto-Restart

The regulator includes cycle-by-cycle current limiting, which prevents the instantaneous inductor current from exceeding ~1350mA.

The IC enters “fault” mode after sustained over-current. If current limit is asserted for more than 32 consecutive cycles (about 20μs), the IC returns to shutdown state and remains in that condition for ~80μs. After that time, the regulator attempts to restart with a normal soft-start cycle. If the fault has not cleared, it shuts down ~10μs later.

If the fault is a short circuit, the initial current limit is ~30% of the normal current limit, which produces a very small drain on the system power source.

Thermal Protection

When the junction temperature of the IC exceeds 150°C, the device turns off all output MOSFETs and remains in a low quiescent current state until the die cools to 130°C before commencing a normal soft-start cycle.

Under-Voltage Lockout (UVLO)

The IC turns off all MOSFETs and remains in a very low quiescent current state until V_{IN} rises above the UVLO threshold.

I²C Interface

The FAN5355’s serial interface is compatible with standard, fast, and HS mode I²C bus specifications. The FAN5355’s SCL line is an input and its SDA line is a bi-directional open-drain output; it can only pull down the bus when active. The SDA line only pulls LOW during data reads and when signaling ACK. All data is shifted in MSB (bit 7) first.

SDA and SCL are normally pulled up to a system I/O power supply (VCCIO), as shown in Figure 1. If the I²C interface is not used, SDA and SCL should be tied to AVIN to minimize quiescent current consumption.

Addressing

FAN5355 has four user-accessible registers:

	Address							
	7	6	5	4	3	2	1	0
VSEL0	0	0	0	0	0	0	0	0
VSEL1	0	0	0	0	0	0	0	1
CONTROL1	0	0	0	0	0	0	1	0
CONTROL2	0	0	0	0	0	0	1	1

Table 9. I²C Register Addresses

Slave Address

In Table 10, A1 and A0 are according to the Ordering Information table on page 2.

7	6	5	4	3	2	1	0
1	0	0	1	0	A1	A0	R/W

Table 10. I²C Slave Address

Bus Timing

As shown in Figure 39, data is normally transferred when SCL is LOW. Data is clocked in on the rising edge of SCL. Typically, data transitions shortly at or after the falling edge of SCL to allow ample time for the data to set up before the next SCL rising edge.

Figure 39. Data Transfer Timing

Each bus transaction begins and ends with SDA and SCL HIGH. A transaction begins with a “START” condition, which is defined as SDA transitioning from 1 to 0 with SCL HIGH, as shown in Figure 40.

Figure 40. Start Bit

A transaction ends with a “STOP” condition, which is defined as SDA transitioning from 0 to 1 with SCL HIGH, as shown in Figure 41.

Figure 41. Stop Bit

During a read from the FAN5355 (Figure 44), the master issues a “Repeated Start” after sending the register address, and before resending the slave address. The “Repeated Start” is a 1 to 0 transition on SDA while SCL is HIGH, as shown in Figure 42.

High-Speed (HS) Mode

The protocols for High-Speed (HS), Low-Speed (LS), and Fast-Speed (FS) modes are identical, except the bus speed for HS mode is 3.4MHz. HS mode is entered when the bus master sends the HS master code 00001XXX after a start condition. The master code is sent in FS mode (less than 400kHz clock) and slaves do not ACK this transmission.

The master then generates a repeated start condition (Figure 42) that causes all slaves on the bus to switch to HS mode. The master then sends I²C packets, as described above, using the HS mode clock rate and timing.

The bus remains in HS mode until a stop bit (Figure 41) is sent by the master. While in HS mode, packets are separated by repeated start conditions (Figure 42).

Figure 42. Repeated Start Timing

Read and Write Transactions

The following figures outline the sequences for data read and write. Bus control is signified by the shading of the packet, defined as

All addresses and data are MSB first.

Symbol	Definition
S	START, see Figure 40.
A	ACK. The slave drives SDA to 0 to acknowledge the preceding packet.
\bar{A}	NACK. The slave sends a 1 to NACK the preceding packet.
R	Repeated START, see Figure 42.
P	STOP, see Figure 41.

Figure 44. Read Transaction

Register Descriptions

Default Values

Each option of the FAN5355 (see *Ordering Information on page 2*) has different default values for the some of the register bits. Table 12 defines both the default values and the bit's type (as defined in Table 13) for each available option.

VSEL0									
Option	7	6	5	4	3	2	1	0	V _{OUT}
00	1	1	0	1	1	0	0	0	1.05
02	1	1	0	1	1	0	0	0	1.05
03	1	1	0	1	0	1	0	0	1.00
07	1	1	0	1	1	0	0	0	1.05
06	1	1	1	1	0	0	0	1	1.80

VSEL1									
Option	7	6	5	4	3	2	1	0	V _{OUT}
00	1	1	1	1	0	0	0	0	1.35
02	1	1	1	0	0	1	0	0	1.20
03	1	1	1	0	0	1	0	0	1.20
07	1	1	1	1	0	0	0	0	1.35
06	1	1	1	1	0	0	0	1	1.80

00, 02	0	0	0	0	0	1	1	1
03	0	0	0	0	0	1	1	1
06, 07	0	0	0	0	0	1	1	1

Table 12. Default Values and Bit Types for VSEL and CONTROL Registers

#	Active bit.	Changing this bit changes the behavior of the converter, as described below.
#	Disabled.	Converter logic ignores changes made to this bit. Bit can be written to and read-back.
#	Read-only.	Writing to this bit through I ² C does not change the read-back value, nor does it change converter behavior.

Table 13. Bit Type Definitions for Table 12.

Bit Definitions

The following table defines the operation of each register bit. Superscript characters define the default state for each option. Superscripts ^{0,2,3,6,7} signify the default values for options 00, 02, 03, 06, and 07, respectively. ^A signifies the default for all options.

Bit	Name	Value	Description
VSEL0 Register Address: 00			
7	EN_DCDC	0	Device in shutdown regardless of the state of the EN pin. This bit is mirrored in VSEL1. A write to bit 7 in either register establishes the EN_DCDC value.
		1 ^A	Device enabled when EN pin is HIGH, disabled when EN is LOW.
6	Reserved ^{0,2,3,6} or DAC6 ⁷	Table 12	Has no effect in options 00, 02, 03, 06, and defaults to 1. In option 07, it is the MSB of the 7-bit DAC value to set V _{OUT} .
5:0	DAC[5:0]		6-bit DAC value to set V _{OUT} . The six LSBs of the 7-bit value for option 07.
VSEL1 Register Address: 01			
7	EN_DCDC	0	Device in shutdown regardless of the state of the EN pin. This bit is mirrored in VSEL0. A write to bit 7 in either register establishes the EN_DCDC value.
		1 ^A	Device enabled when EN pin is HIGH, disabled when EN is LOW.
6	Reserved ^{0,2,3,6} or DAC6 ⁷	Table 12	Has no effect in options 00, 02, 03, 06, and defaults to 1. In option 07, it is the MSB of the 7-bit DAC value to set V _{OUT} .
5:0	DAC[5:0]		6-bit DAC value to set V _{OUT} . The six LSBs of the 7-bit value for option 07.
CONTROL1 Register Address: 02			
7:6	Reserved	10 ^{0,2,5,6} 00 ³	Vendor ID bits. Writing to these bits has no effect on regulator operation. These bits can be used to distinguish between vendors via I ² C.
5	EN_SYNC	0 ^A	Disables external signal on SYNC from affecting the regulator.
		1	When a valid frequency is detected on SYNC, the regulator synchronizes to it and PFM is disabled, except when MODE = 00, VSEL pin = LOW, and HW_nSW = 1.
4	HW_nSW	0	V _{OUT} is controlled by VSEL1. Voltage transitions occur by writing to the VSEL1, then setting the GO bit.
		1 ^A	V _{OUT} is programmed by the VSEL pin. V _{OUT} = VSEL1 when VSEL is HIGH, and VSEL0 when VSEL is LOW.
3:2	MODE_CTRL	00 ^A	Operation follows MODE0, MODE1.
		01	NPFM with automatically transitions to PWM, regardless of VSEL.
		10	PFM disabled (forced PWM), regardless of VSEL.
		11	EPFM (F _{SW(MIN)} = 25kHz) with automatically transitions to PWM, regardless of VSEL.
1	MODE1	0 ^A	PFM disabled (forced PWM) when regulator output is controlled by VSEL1.
		1	NPFM with automatic transitions to PWM when regulator output is controlled by VSEL1.
0	MODE0	0 ^A	NPFM with automatic transitions to PWM when VSEL is LOW. Changing this bit has no effect on the operation of the regulator.
		1	
CONTROL2 Register Address: 03			
7	GO	0 ^A	This bit has no effect when HW_nSW = 1. At the end of a V _{OUT} transition, this bit is reset to 0.
		1	Starts a V _{OUT} transition if HW_nSW = 0.
6	OUTPUT_DISCHARGE	0 ^A	When the regulator is disabled, V _{OUT} is not discharged.
		1	When the regulator is disabled, V _{OUT} discharges through an internal pull-down.
5	PWROK (read only)	0	V _{OUT} is not in regulation or is in current limit.
		1	V _{OUT} is in regulation.
4:3	PLL_MULT	00 ^A	f _{SW} = f _{SYNC} when synchronization is enabled.
		01	f _{SW} = 2 X f _{SYNC} when synchronization is enabled.
		10	f _{SW} = 3 X f _{SYNC} when synchronization is enabled.
		11	f _{SW} = 4 X f _{SYNC} when synchronization is enabled.
2:0	DEFSLEW	000	V _{OUT} slews at 0.15mV/μs during positive V _{OUT} transitions.
		001	V _{OUT} slews at 0.30mV/μs during positive V _{OUT} transitions.
		010	V _{OUT} slews at 0.60mV/μs during positive V _{OUT} transitions.
		011	V _{OUT} slews at 1.20mV/μs during positive V _{OUT} transitions.
		100	V _{OUT} slews at 2.40mV/μs during positive V _{OUT} transitions.
		101	V _{OUT} slews at 4.80mV/μs during positive V _{OUT} transitions.
		110	V _{OUT} slews at 9.60mV/μs during positive V _{OUT} transitions.
		111 ^A	Positive V _{OUT} transitions use single-step mode (see Figure 37).

DISCLAIMER

FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION, OR DESIGN. FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS. THESE SPECIFICATIONS DO NOT EXPAND THE TERMS OF FAIRCHILD'S WORLDWIDE TERMS AND CONDITIONS, SPECIFICALLY THE WARRANTY THEREIN, WHICH COVERS THESE PRODUCTS.

LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF FAIRCHILD SEMICONDUCTOR CORPORATION.

As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.
2. A critical component in any component of a life support device, or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

PRODUCT STATUS DEFINITIONS

Definition of Terms

Datasheet Identification	Product Status	Definition
Advance Information	Formative / In Design	This datasheet contains the design specifications for product development. Specifications may change in any manner without notice.
Preliminary	First Production	This datasheet contains preliminary data; supplementary data will be published at a later date. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve design.
No Identification Needed	Full Production	This datasheet contains final specifications. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve the design.
Obsolete	Not In Production	This datasheet contains specifications on a product that is discontinued by Fairchild Semiconductor. The datasheet is for reference information only.
