LINEAR TECHNOLOGY

100kHz, 1.25A Switching Regulator with Catch Diode

FEATURES

- **Catch Diode Included in Package**
- Wide Input Voltage Range: 3V to 30V
- Low Quiescent Current: 6mA
- **Internal 1.25A Switch**
- Very Few External Parts Required
- Self-Protected Against Overloads
- **Operates in Nearly All Switching Topologies**
- Shutdown Mode Draws Only 50μA Typical Current
- Can Be Externally Synchronized

APPLICATIONS

- 3.3V-to-5V and 5V-to-12V Boost Converters
- Negative-to-Positive Converter
- SEPIC Converter (Input Can Be Greater or Less Than Output)
- Battery Charger

DESCRIPTION

The LT®1572 is a 1.25A 100kHz monolithic switching regulator with on-board switch and catch diode included in one package. It combines an LT1172 with a 1A Schottky catch diode. The LT1572 can be operated in all standard switching configurations, including boost, buck, SEPIC, flyback, forward, inverting and "Cuk". All necessary control, oscillator and protection circuitry is included on the die with the high efficiency switch. This makes the part extremely easy to use and provides "bustproof" operation similar to that obtained with 3-pin linear regulators.
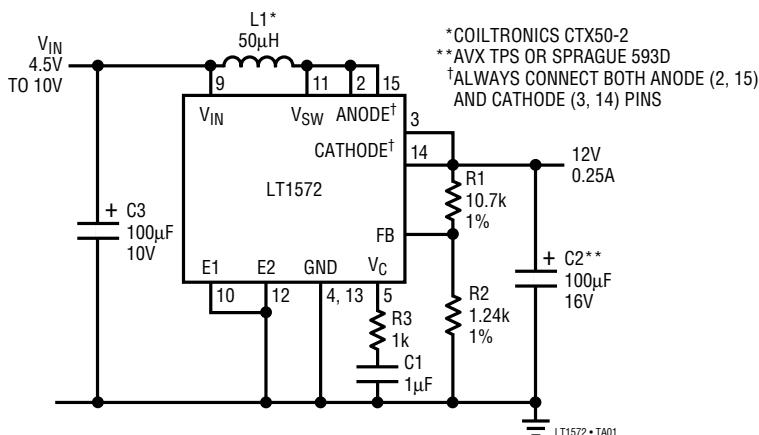

The LT1572 operates with supply voltages from 3V to 30V and draws only 6mA quiescent current. It can deliver load power up to 15W with no external power devices. By utilizing a current mode switching technique, the LT1572 achieves excellent response to load and line transients.

The LT1572 has many unique features not found on the more difficult to use control chips presently available. It uses adaptive anti-sat switch drive to allow very wide ranging load currents with no loss in efficiency. An externally activated shutdown mode reduces total supply current to 50μA typical for standby operation. External synchronizing of switching frequency is possible, with a range of 120kHz to 160kHz.
LT, LTC and LT are registered trademarks of Linear Technology Corporation.

    Operating .... 0°C to 100°C
    Short Circuit .... 0°C to 125°C
Storage Temperature Range .... −65°C to 150°C
Lead Temperature (Soldering, 10 sec)................ 300°C

DIODE

Average Forward Current 1A
Peak Repetitive Forward Current 2A
Peak Non-Repetitive Forward Current...................... 3A
Peak Repetitive Reverse Voltage........................... 20V
Continuous (Average) Reverse Voltage 15V
Operating Junction Temperature .... 125°C

Note 1: Minimum effective switch "on" time for the LT1572 (in current limit only) is ≈ 0.6µs. This limits the maximum safe input voltage during an output shorted condition. Buck mode and inverting mode input voltage during an output shorted condition is limited to:

$$V_{IN}\ (max,\ output\ shorted) = 15V + \frac{R \times I_L + V_f}{t \times f}$$
buck and inverting mode

R = Inductor DC resistance

I_L = 2.5A

V_f = Output catch diode forward voltage at I_L

t = 0.6µs, f = 100kHz switching frequency

ORDER PART NUMBER

LT1572CS

Consult factory for Industrial and Military grade parts.

Maximum input voltage can be increased by increasing R or V_f.

External current limiting such as that shown in AN19, Figure 39, will provide protection up to the full supply voltage rating. C1 in Figure 39 should be reduced to 200pF.

Transformer designs will tolerate much higher input voltages because leakage inductance limits rate of rise of current in the switch. These designs must be evaluated individually to assure that current limit is well controlled up to maximum input voltage.

Boost mode designs are never protected against output shorts because the external catch diode and inductor connect input to output.

ELECTRICAL CHARACTERISTICS V_{IN} = 15V, V_C = 0.5V, V_{FB} = V_{REF}, output pin open, unless otherwise noted.

ELECTRICAL CHARACTERISTICS V_{IN} = 15V, V_C = 0.5V, V_{FB} = V_{REF}, output pin open, unless otherwise noted.

The ● denotes the specifications which apply over the full operating temperature range, 0°C to 100°C for the regulator chip and 0°C to 125°C for the diode.

Note 1: Measured with V_C in hi clamp, V_{FB} = 0.8V. I_{SW} = 1A.

Note 2: For duty cycles (DC) between 50% and 80%, minimum guaranteed switch current is given by I_{LIM} = 0.833 (2 – DC).

Note 3: Minimum input voltage for isolated flyback mode is 7V.

Note 4: Because the catch diode has a peak repetitive reverse voltage of 20V, diode breakdown may be the limiting factor on input voltage or switch voltage in many applications.

Note 5: See graphs for guaranteed forward voltage and reverse leakage current over temperature. Parameters are 100% tested at 25°C and guaranteed at other temperatures by design and QA sampling.

Note 6: Package soldered to FR4 board with ≥1oz copper and an internal or backside plane underneath the package to aid thermal transfer. Diode is partly thermally coupled to regulator section. See Application Information section for details on thermal calculations.

BLOCK DIAGRAM

*ALWAYS CONNECT E1 TO GROUND

OPERATION

The LT1572 is a current mode switcher. This means that switch duty cycle is directly controlled by switch current rather than by output voltage. Referring to the block diagram, the switch is turned "on" at the start of each oscillator cycle. It is turned "off" when switch current reaches a predetermined level. Control of output voltage is obtained by using the output of a voltage sensing error amplifier to set current trip level. This technique has several advantages. First, it has immediate response to input voltage variations, unlike ordinary switchers which have notoriously poor line transient response. Second, it reduces the 90° phase shift at mid-frequencies in the energy storage inductor. This greatly simplifies closed-loop frequency compensation under widely varying input voltage or output load conditions. Finally, it allows simple pulse-by-pulse current limiting to provide maximum switch protection under output overload or short conditions.

A low dropout internal regulator provides a 2.3V supply for all internal circuitry on the LT1572. This low dropout design allows input voltage to vary from 3V to 40V with virtually no change in device performance. A 100kHz oscillator is the basic clock for all internal timing. It turns "on" the output switch via the logic and driver circuitry. Special adaptive anti-sat circuitry detects onset of saturation in the power switch and adjusts driver current instantaneously to limit switch saturation. This minimizes driver dissipation and provides very rapid turn-off of the switch.

A 1.2V bandgap reference biases the positive input of the error amplifier. The negative input is brought out for output voltage sensing. This feedback pin has a second function; when pulled low with an external resistor, it programs the LT1572 to disconnect the main error amplifier output and connects the output of the flyback amplifier

OPERATION

to the comparator input. The LT1572 will then regulate the value of the flyback pulse with respect to the supply voltage.[1] This flyback pulse is directly proportional to output voltage in the traditional transformer coupled flyback topology regulator. By regulating the amplitude of the flyback pulse, the output voltage can be regulated with no direct connection between input and output. The output is fully floating up to the breakdown voltage of the transformer windings. Multiple floating outputs are easily obtained with additional windings. A special delay network inside the LT1572 ignores the leakage inductance spike at the leading edge of the flyback pulse to improve output regulation.

The error signal developed at the comparator input is brought out externally. This pin (V_C) has four different functions. It is used for frequency compensation, current limit adjustment, soft starting, and total regulator shutdown. During normal regulator operation this pin sits at a voltage between 0.9V (low output current) and 2.0V (high output current). The error amplifiers are current output (g_m) types, so this voltage can be externally clamped for adjusting current limit. Likewise, a capacitor coupled external clamp will provide soft start. Switch duty cycle goes to zero if the V_C pin is pulled to ground through a diode, placing the LT1572 in an idle mode. Pulling the V_C pin below 0.15V causes total regulator shutdown, with only 50µA supply current for shutdown circuitry biasing. See AN19 for full application details.

E1 and E2 Pins

The LT1572 has the emitters of the power transistor brought out separately from the ground pin. This eliminates errors due to ground pin voltage drops and allows the user to reduce switch current limit 2:1 by leaving the second emitter (E2) disconnected. The first emitter (E1) should always be connected to the ground pin. Note that switch "on" resistance doubles when E2 is left open, so efficiency will suffer somewhat when switch currents exceed 300mA. Also, note that chip dissipation will actually *increase* with E2 open during normal load operation, even though dissipation in current limit mode will *decrease*.

---

[1]See note under block diagram.

Other Application Help

More circuits and application help for the LT1572 can be found in the LT1172 data sheet, both in loose form and in the *1994 Linear Databook Volume III*. Extensive additional help is contained in Application Note 19. All application circuits using the LT1172 can also use the LT1572 as long as the 20V maximum reverse voltage of the diode is not exceeded. A CAD program called SwitcherCAD is also available. This program can be used with the LT1572 by simply treating the LT1572 as an LT1172 and ignoring the predicted die temperature results obtained from SwitcherCAD itself.

Thermal Management

Thermal management is particularly important with the LT1572 because both switch and diode power dissipation increase rapidly at low input voltage when using the popular boost topology. Regulator and diode die temperature must be calculated *separately* because they are not connected to an isothermal plane inside the package. Diode *plus* regulator thermal resistance is approximately 70°C/W when the LT1572 is soldered to 1oz copper traces over an internal or backside copper plane using FR4 board material. However, individual calculation of die temperature must take thermal coupling into account. To accomplish this, thermal resistance is broken into two sections, a common (coupled) section and a second uncoupled section. Die temperatures are calculated from:

$$T_{REG} = T_A + P_{REG} \, (90°C/W) + P_{DIODE} \, (45°C/W)$$

$$T_{DIODE} = T_A + P_{DIODE} \, (90°C/W) + P_{REG} \, (45°C/W)$$

T_A = ambient temperature
T_{REG} = regulator die temperature
T_{DIODE} = diode die temperature
P_{REG} = total regulator power dissipation
P_{DIODE} = diode power dissipation

The following formulas can be used as a rough guide to calculate LT1572 power dissipation. For more details, the reader is referred to Application Note 19 (AN19), "Efficiency Calculations" section.

OPERATION

Average supply current (including driver current) is:

$I_{IN} \approx 6mA + I_{SW}(0.004 + DC/40)$

I_{SW} = switch current
DC = switch duty cycle

Switch power dissipation is given by:

$P_{SW} = (I_{SW})^2 \times R_{SW} \times DC$

R_{SW} = LT1572 switch "on" resistance (1Ω maximum)

Total power dissipation is the sum of supply current times input voltage plus switch power:

$P_{REG} = I_{IN} \times V_{IN} + P_{SW}$

In a typical example, using a boost converter to generate 12V at 0.12A from a 5V input, duty cycle is approximately 60%, and switch current is about 0.65A, yielding:

$I_{IN} = 6mA + 0.65(0.004 + DC/40) = 18mA$

$P_{SW} = (0.65)^2 \times 1\Omega \times 0.6 = 0.25W$

$P_{REG} = 5V \times 0.018A + 0.25 = 0.34W$

Approximate diode power dissipation for boost and buck converters is shown below. For other topologies or more accurate results, see Application Note 19 or use SwitcherCAD.

Boost: $P_{DIODE} = I_{OUT} \times V_f$
Buck: $P_{DIODE} = I_{OUT} \times V_f \times (V_{IN} - V_{OUT})/V_{IN}$

V_f = diode forward voltage at a current equal to I_{OUT} for a buck converter and $I_{OUT} \times V_{OUT}/V_{IN}$ for a boost converter.

In most applications, full load current is used to calculate die temperature. However, if overload conditions must also be accounted for, three approaches are possible. First, if loss of regulated output is acceptable under overload conditions, the internal *thermal limit* of the LT1572 will protect the die in most applications by shutting off switch current. *Thermal limit is not a tested parameter*, however, and should be considered only for noncritical applications with temporary overloads.

The second approach for lower current applications is to leave the second switch emitter (E2) open. This increases

switch "on" resistance by 2:1, but reduces switch current limit by 2:1 also, resulting in a net 2:1 reduction in I²R switch dissipation under current limit conditions.

The third approach is to clamp the V_C pin to a voltage less than its internal clamp level of 2V. The LT1172 switch current limit is zero at approximately 1V on the V_C pin and 2A at 2V on the V_C pin. Peak switch current can be externally clamped between these two levels with a diode. See AN19 for details.

Diode Characteristics

The catch diode used in the LT1572 is a power Schottky diode with a very low storage time and low forward voltage. This gives good efficiency in switching regulator applications, but some thought must be given to maximum operating voltage and high temperature reverse leakage. *Peak repetitive reverse voltage rating on the diode is 20V.* In a boost converter, maximum diode reverse voltage is equal to regulated output voltage, so this limits maximum output voltage to 20V. In a negative-to-positive converter, maximum diode voltage will be equal to the sum of output voltage *plus* input voltage. Use the equations in Application Note 19 or SwitcherCAD or calculate maximum diode voltage for other topologies.

Diode reverse leakage increases rapidly with temperature. This leakage is not high enough to significantly impact efficiency or diode power dissipation, but it can be of concern in shutdown mode if the diode is connected in such a way that the leakage adds to regulator shutdown current. Use the graphs of diode leakage versus voltage and temperature to ensure proper high temperature system performance.

The LT1572 diode is internally bonded to more than two package pins to reduce internal bond wire currents. *All pins must be used to prevent excessive current in the individual internal bond wires.* This is important in low load current applications because the LT1572 will draw high surge currents during start-up (to charge the output capacitor) even with no output load current.
