4 Circuit Description

This flyback power supply was designed around the TNY278PN (U1 in Figure 2). The output voltage is sensed and fed back to U1 through optocoupler U2. That feedback is used by U1 to maintain constant voltage (CV) regulation of the output.

4.1 Input Rectification and Filtering

Diodes D1–D4 rectify the AC input. Capacitors C1 and C2 filter the rectified DC. Inductor L1, C1 and C2 form a pi filter that attenuates differential mode conducted EMI.

4.2 TNY278PN Operation

The TNY278PN device (U1) integrates an oscillator, a switch controller, startup and protection circuitry, and a power MOSFET, all on one monolithic IC.

One side of the power transformer (T1) primary winding is connected to the positive leg of C2, and the other side is connected to the DRAIN pin of U1. At the start of a switching cycle, the controller turns the MOSFET on, and current ramps up in the primary winding, which stores energy in the core of the transformer. When that current reaches the limit threshold, the controller turns the MOSFET off. Due to the phasing of the transformer windings and the orientation of the output diode, the stored energy then induces a voltage across the secondary winding, which forward biases the output diode, and the stored energy is delivered to the output capacitor. When the MOSFET turns off, the leakage inductance of the transformer induces a voltage spike on the drain node. The amplitude of that spike is limited by an RCD clamp network that consists of D5, C4 and R2. Resistor R1 and VR1 provide hard clamping of the drain voltage, only conducting during output overload. Resistor R2 also limits the reverse current that flows through D5 when the MOSFET turns on. This allows a slow, low-cost, glass passivated diode (with a recovery time of $\leq 2 \mu\text{s}$.) to be used for D5, which improves conducted EMI and efficiency.

Using ON/OFF control, U1 skips switching cycles to regulate the output voltage, based on feedback to its EN/UV pin. The EN/UV pin current is sampled, just prior to each switching cycle, to determine if that switching cycle should be enabled or disabled. If the EN/UV pin current is $< 115 \mu\text{A}$, the next switching cycle begins, and is terminated when the current through the MOSFET reaches the internal current limit threshold. To evenly spread switching cycles, preventing group pulsing, the EN pin threshold current is modulated between $115 \mu\text{A}$ and $60 \mu\text{A}$ based on the state during the previous cycle. A state-machine within the controller adjusts the MOSFET current limit threshold to one of four levels, depending on the load being demanded from the supply. As the load on the supply drops, the current limit threshold is reduced. This ensures that the effective switching frequency stays above the audible range until the transformer flux density is low. When the standard production technique of dip varnishing is used for the transformer, audible noise is practically eliminated.

4.3 Output Rectification and Filtering

Diode D7 rectifies the output of T1. Output voltage ripple was minimized by using a low ESR capacitor for C10 (see Section 6 for component part numbers and values). A post filter (ferrite bead L2 and C11) attenuates the high frequency switching noise.

4.4 Feedback and Output Voltage Regulation

The supply's output voltage regulation set point is set by the voltage that develops across Zener diode VR3, R6 and the LED in opto-coupler U2. The value of R4 was calculated to bias VR3 to about 0.5 mA when it goes into reverse avalanche conduction. This ensures that it is operating close to its rated knee current. Resistor R6 limits the maximum current during load transients. The values of R4 and R6 can both be varied slightly to fine-tune the output regulation set point. When the output voltage rises above the set point, the LED in U2 becomes forward biased. On the primary side, the photo-transistor of U2 turns on and draws current out of the EN/UV pin of U1. Just before the start of each switching cycle, the controller checks the EN/UV pin current. If the current flowing out of the EN/UV pin is greater than 115 μ A, that switching cycle will be disabled. As switching cycles are enabled and disabled, the output voltage is kept very close to the regulation set point. For greater output voltage regulation accuracy, a reference IC such as a TL431 can be used in place of VR3.

4.5 Output Overvoltage Shutdown

The *TinySwitch-III* family of ICs can detect overvoltage on the output of the supply and latch off. This protects the load in an open feedback loop fault condition, such as the failure of the optocoupler. Overvoltage on the output is detected through the BP/M pin and the bias winding on the transformer. The bias winding voltage is determined by the reflection of the output voltage through the turns ratio of the transformer. Therefore, an overvoltage on the output will be reflected onto the bias winding. The overvoltage threshold is the sum of the breakdown voltage of Zener diode VR2 and the BP/M pin voltage (28 V + 5.8 V). If the output voltage becomes abnormally high, the voltage on the bias winding will exceed the threshold voltage and excess current will flow into the BP/M pin. The latching shutdown circuit is activated when current into the BP/M pin exceeds 5 mA. Resetting a latched shutdown requires removing the AC input from the supply long enough to allow the input capacitors (C1 and C2) to discharge, and the BP/M pin voltage to drop below 2 V. Resistors R7 and R3 provide additional filtering of the bias voltage, with R3 also limiting the maximum current into the BYPASS pin in an OV condition

4.6 EMI Design Aspects

An input pi filter (C1, L1 and C2) attenuates conducted, differential mode EMI noise. Shielding techniques (*E-Shield*[™]) were used in the construction of T1 to reduce common mode EMI displacement currents. Resistor R2 and capacitor C4 dampen out some of the high frequency ringing that occurs when the MOSFET turns off. When combined with the IC's frequency jitter function, these techniques produce excellent conducted and radiated EMI performance (see Section 12 of this report).

4.7 Peak Primary Current Limit Selection

The value of the capacitor installed on the BP/M pin allows the current limit of U1 to be selected. The power supply designer can change the current limit of the MOSFET by simply changing the capacitance value connected to the BP/M pin (see the *TinySwitch-III* data sheet for more details).

- Installing a 0.1 μF capacitor on the BP/M pin selects the standard current limit of the IC, and is the normal choice for enclosed adapter applications.
- Installing a 1 μF capacitor on the BP/M pin reduces the MOSFET current limit, which lowers conduction losses and improves efficiency (at the expense of reducing the maximum power capability of the IC).
- A 10 μF capacitor on the BP/M pin will raise the MOSFET current limit and extend the power capability of the IC (for higher power applications that do not have the thermal constraints of an enclosed adapter, or to supply short-duration, peak load demands).

The EP91 demonstration board comes with a 0.1 μF capacitor installed as C7, which causes U1 to select the standard current limit specified in the *TinySwitch-III* data sheet. If C7 were replaced by a 1 μF capacitor (C8 in the BOM, section 6), the current limit of U1 will be the same as the standard current limit for a TNY277 device. If a 10 μF capacitor is installed, the current limit of U1 will be the same as the standard current limit for a TNY279 device. The flexibility of this option enables the designer to do three things. First, it allows the designer to measure the effect of switching to an adjacent device without actually removing and replacing the IC. Second, it allows a larger device to be used with a lower current limit, for higher efficiency. Third, it allows a smaller device to be used with a higher current limit in a design when higher power is not required on a continual basis, which effectively lowers the cost of the supply.

4.8 UV Lockout

The EP91 circuit board has a location where an optional under-voltage (UV) lockout detection resistor (R5) can be installed. When installed, MOSFET switching is disabled at startup until current into the EN/UV pin exceeds 25 μA . This allows the designer to set the input voltage at which MOSFET switching will be enabled by choosing the value of R5. For example, a value of 3.6 M Ω requires an input voltage of 65 VAC (92 VDC across C2) before the current into the EN/UV pin exceeds 25 μA . The UV detect function also prevents the output of the power supply from glitching (trying to restart) after output regulation is lost (during shutdown), by disabling MOSFET switching until the input voltage rises above the under-voltage lockout threshold.

9 Performance Data

The ON/OFF control scheme employed by *TinySwitch-III* yields virtually constant efficiency across the 25% to 100% load range required for compliance with EPA, CEC, CECP and AGO energy efficiency standards for external power supplies (EPS). Even at loads below 10% of the supply's full rated output power, efficiency remains above 65%, providing excellent standby performance for applications that require it. This performance is automatic with ON/OFF control. There are no special burst modes that require the designer to consider specific thresholds within the load range in order to achieve compliance with global energy efficiency standards.

All measurements performed at room temperature, 60 Hz input frequency.

9.2 Active Mode CEC Measurement Data

In the state of California, after July 1, 2006, all single-output EPS adapters – including those sold with the products they power – must meet the California Energy Commission (CEC) requirement for minimum active-mode efficiency and no-load input power consumption. Minimum active-mode efficiency is defined as the average efficiency at 25, 50, 75 and 100% of rated output power printed on the nameplate of the supply:

Nameplate Output (P_o)	Minimum Efficiency in Active Mode of Operation
< 1 W	$0.49 \times P_o$
≥ 1 W to ≤ 49 W	$0.09 \times \ln(P_o) + 0.49$ [ln = natural log]
> 49 W	0.84 W

For adapters that are single input voltage only, the measurements are to be made at the nominal rated input voltage (115 VAC or 230 VAC). For universal input adapters, the measurements are to be made at both nominal input voltages (115 VAC and 230 VAC).

To comply with the standard, the average of the four efficiency measurements must be greater than or equal to the efficiency specified by the standard.

Percent of Full Load	Efficiency (%)	
	115 VAC	230 VAC
25	75	74.5
50	78.5	78.8
75	78.8	78.5
100	78	79.1
Average	77.6	77.7
Required CEC minimum average efficiency (%)	71.3	

From these results it is apparent that the efficiency of this design easily exceeds the required 71.3 %. More states within the USA, and many other countries around the world are adopting similar energy efficiency standards (based on the original Energy Star standard). 9.5 Available Standby Output Power

The chart below shows the available output power versus line voltage at input power consumption levels of 1, 2 and 3 watts (respectively). Again, this performance illustrates the value of ON/OFF control, as it automatically maintains a high efficiency, even during very light loading. This simplifies complying with standby requirements that specify that a fair amount of power be available to the load at low input power consumption levels. The *TinySwitch-III* ON/OFF control scheme maximizes the amount of output power available to the load in standby operation when the allowable input power is fixed at a low value. This simplifies the design of products such as printers, set-top boxes, DVD players, etc. that must meet stringent standby power consumption requirements.

10 Thermal Performance

Temperature measurements of key components were taken using T-type thermocouples. The thermocouples were soldered directly to a SOURCE pin of the TNY278PN device and to the cathode of the output rectifier. The thermocouples were glued to the output capacitor and to the external core and winding surfaces of transformer T1.

The unit was sealed inside a large box to eliminate any air currents. The box was placed inside a thermal chamber. The ambient temperature within the large box was raised to 50 °C. The unit was then operated at full load and the temperature measurements were taken after they stabilized for 1 hour at 50 °C.

Temperature (°C)		
Item	85 VAC	265 VAC
Ambient	50*	50*
TNY278PNP (U1)	96.1	92.8
Transformer (T1)	77.8	80
Output Rectifier (D7)	101	100
Output Capacitor (C10)	68.2	66.8

*To simulate operation inside sealed enclosure at 40 °C external ambient.

These results show that all key components have an acceptable rise in temperature.

11.5 Output Ripple Measurements

11.5.1 Ripple Measurement Technique

A modified oscilloscope test probe was used to take output ripple measurements, in order to reduce the pickup of spurious signals. Using the probe adapter pictured in Figure 22, the output ripple was measured with a 1 μF electrolytic, and a 0.1 μF ceramic capacitor connected as shown.

12 Line Surge

Differential input line surge (1.2/50 μ s) testing was completed on a single test unit to IEC61000-4-5. Input voltage was set at 230 VAC / 60 Hz. Output was loaded at full load and operation was verified following each surge event.

1 kV Differential	90°	2 Ω	10	PASS
2 kV Common Mode	90°	12 Ω	10	PASS

13 Conducted EMI

Conducted emissions tests were performed at 115 VAC and 230 VAC at full load (12 V, 1 A). Measurements were taken with an Artificial Hand connected and a floating DC output load resistor. A DC output cable was included.

Composite EN55022B / CISPR22B conducted limits are shown. In all cases there was excellent (>10 dB) margin.

14 Audible Noise

An open-frame (no enclosure) unit was tested with an Audio Precision Analyzer, using a microphone positioned one inch from the core of transformer T1. The test was done with the unit in an acoustically isolated and dampened chamber. The load was adjusted until a maximum reading was obtained.

35 dBrA is considered the acceptable limit for frequencies below 18 kHz. An enclosure will typically further reduce measurable acoustic noise levels by an additional 10 dBrA.

15 Extended and Reduced Current Limit (I_{LIMIT}) Operation

Additional capacitors (C8 and C9 on the BOM in Section 6) have been included in the DAK-91 kit for the convenience of trying out the $I_{LIMIT+1}$ and $I_{LIMIT-1}$ operation of TNY278PN in the RD-91 reference board. When C7 (0.1 μ F) is replaced with a 10 μ F capacitor (C9), the TNY278PN will operate in the $I_{LIMIT+1}$ mode, which increases the maximum primary current limit from the standard maximum limit of 0.55 A to 0.65 A (equal to that of a TNY279PN). This allows a TNY278PN to deliver from 15% to 25% more output power (depending on the output voltage and current).

CAUTION: Because RD-91 was designed for standard I_{LIMIT} operation, it should not be loaded with more than 1.25 A at an elevated temperature for very long (a few minutes) when verifying the performance of TNY278PN in the $I_{LIMIT+1}$ mode, since the other power components (transformer, input bulk capacitors, output diode, output capacitors and primary clamp network) are not sized for sustained operation at more than 12 W.

When C7 is replaced with a 1 μ F capacitor (C8), the TNY278PN will operate in the $I_{LIMIT-1}$ mode, which reduces the maximum current limit from the standard maximum limit of 0.55 A to 0.45 A (equal to that of a TNY277PN). Although this reduces the maximum output power that the supply can deliver, it typically will increase the efficiency, especially at lower output power levels. To take the fullest advantage of the increase in efficiency that can be obtained from $I_{LIMIT-1}$ operation, the power transformer would need to be redesigned slightly.

16 TNY277PN and TNY279PN Operation in RD-91

A TNY277PN device used in the $I_{LIMIT+1}$ mode (a 10 μ F installed in place of C7) will work in the RD-91 reference board, and deliver output power equal to that of a TNY278PN device. This flexibility allows a design engineer the option of using a lower cost part in applications with less demanding thermal requirements.

A TNY279PN device used in the $I_{LIMIT-1}$ mode (a 1 μ F installed in place of C7) will deliver the same output power as a TNY278PN in the standard I_{LIMIT} configuration. This can improve efficiency and lower the temperature rise of the device, which can give greater thermal margin to a design that must operate in high ambient temperature environments.

17 OVP Operation Verification

While the RD-91 is in normal operation, monitor the output with a storage oscilloscope. To cause an overvoltage condition to occur, short circuit the optocoupler LED (as shown below) to open the feedback control loop. The oscilloscope will capture the output voltage rising until the increasing voltage across VR2 causes it to conduct, and the TNY278PN device latches off. To reset the OVP latch, the AC input power must be removed long enough to allow the input bulk capacitors to fully discharge.
