ANALOG DEVICES

Xstream™ 6.5 Gbps Quad Buffer Mux/Demux

AD8158

FEATURES

- Quad 2:1 mux/1:2 demux
- Optimized for dc to 6.5 Gbps NRZ data
- Per-lane P/N pair inversion for routing ease
- Programmable input equalization
  - Compensates up to 40 inches of FR4
- Loss-of-signal detection
- Programmable output pre-emphasis up to 12 dB
- Programmable output levels with squelch and disable
- Accepts ac-coupled or dc-coupled differential CML inputs
- 50 Ω on-chip termination
- 1:2 demux supports unicast or bicast operation
- Port-level loopback
- Port or single lane switching
- 1.8 V to 3.3 V flexible core supply
- User-settable I/O supply from V_{CC} to 1.2 V
- Low power, typically 2.0 W in basic configuration
- 100-lead LFCSP
- –40°C to +85°C operating temperature range

APPLICATIONS

- Low cost redundancy switch
- SONET OC48/SDH16 and lower data rates
- XAUI/GbE/FC/Infiniband over backplane
- OIF CEI 6.25 Gbps over backplane
- Serial data-level shift
- 4-/8-/12-lane equalizers or redrivers

FUNCTIONAL BLOCK DIAGRAM

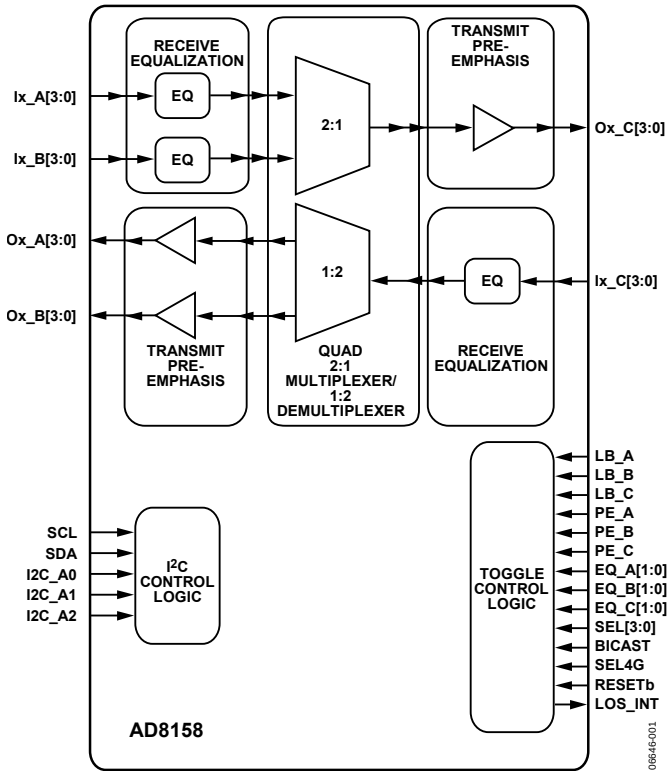

Figure 1.

GENERAL DESCRIPTION

The AD8158 is an asynchronous, protocol-agnostic, quad-lane 2:1 switch with a total of 12 differential CML inputs and 12 differential CML outputs. The signal path supports NRZ signaling with data rates up to 6.5 Gbps per lane. Each lane offers programmable receive equalization, programmable output pre-emphasis, programmable output levels, and loss-of-signal detection.

The nonblocking switch-core of the AD8158 implements a 2:1 multiplexer and 1:2 demultiplexer per lane and supports independent lane switching through the four select pins, SEL[3:0]. Each port is a four-lane link. Every lane implements an asynchronous path supporting dc to 6.5 Gbps NRZ data, fully independent of other lanes. The AD8158 has low latency and very low lane-to-lane skew.

The main application of the AD8158 is to support redundancy on both the backplane and the line interface sides of a serial link. The demultiplexing path implements unicast and bicast capability, allowing the part to support either 1 + 1 or 1:1 redundancy.

The AD8158 is also suited for testing high speed serial links because of its ability to duplicate incoming data. In a port-monitoring application, the AD8158 can maintain link-connectivity with a pass-through connection from Port C to Port A while sending a duplicate copy of the data to test equipment on Port B.

The rich feature set of the AD8158 can be controlled either through external toggle pins or by setting on-chip control registers through the I²C® interface.

REVISION HISTORY

6/08—Revision 0: Initial Version

SPECIFICATIONS

V_{CC} = V_{TTI} = V_{TTO}= 1.8 V, DV_{CC} = 3.3 V, V_{EE} = 0 V, R_L = 50 Ω, basic configuration[1], data rate = 6.5 Gbps, ac-coupled differential input swing = 800 mV p-p, T_A = 25°C, unless otherwise noted.

Table 1.

Parameter	Conditions	Min	Typ	Max	Unit
DYNAMIC PERFORMANCE					
Data Rate/Channel (NRZ)		DC		6.5	Gbps
Deterministic Jitter (No Channel)	Data rate = 6.5 Gbps, EQ enabled		20		ps p-p
Random Jitter (No Channel)	RMS, data rate = 6.5 Gbps		1		ps
Residual Deterministic Jitter with Receive Equalization	Data rate 6.5 Gbps, 20 inch FR4		30		ps p-p
	Data rate 6.5 Gbps, 40 inch FR4		40		ps p-p
Residual Deterministic Jitter with Transmit Pre-Emphasis	Data rate 6.5 Gbps, 10 inch FR4		35		ps p-p
	Data rate 6.5 Gbps, 30 inch FR4		42		ps p-p
Propagation Delay	50% input to 50% output (maximum EQ)		700		ps
Lane-to-Lane Skew	Signal path and switch architecture is balanced and symmetric (maximum EQ)		90		ps
Switching Time	50% logic switching to 50% output data		150		ns
Output Rise/Fall Time	20% to 80% (PE = lowest setting)		62		ps
INPUT CHARACTERISTICS					
Differential Input Voltage Swing	V_{ICM}[2] = V_{CC} − 0.6 V, V_{CC} = V_{MIN} to V_{MAX}, T_A = T_{MIN} to T_{MAX}, LOS threshold register = 0x10, LOS control register = 0x05	200		2000	mV p-p
Differential Sensitivity with Default LOS Setting			300		mV p-p
Input Voltage Range	Single-ended absolute voltage level, V_L minimum		V_{EE} + 0.6		V
	Single-ended absolute voltage level, V_H maximum		V_{CC} + 0.3		V
OUTPUT CHARACTERISTICS					
Output Voltage Swing	Differential, PE = 0, default output level, @ dc	590	725	820	mV p-p
Output Voltage Range	Single-ended absolute voltage level, TX_HEADROOM = 0; V_L minimum		V_{CC} − 1.1		V
	Single-ended absolute voltage level, TX_HEADROOM = 0; V_H maximum		V_{CC} + 0.6		V
	Single-ended absolute voltage level, TX_HEADROOM = 1; V_L minimum		V_{CC} − 1.3		V
	Single-ended absolute voltage level, TX_HEADROOM = 1; V_H maximum		V_{CC} + 0.6		V
Output Current	Port A/B/C, PE_A/B/C = minimum		16		mA
Output Current	Port A/B/C, PE_A/B/C = 6 dB, V_{OD} = 800 mV p-p		32		mA
TERMINATION CHARACTERISTICS					
Resistance	Differential, V_{CC} = V_{MIN} to V_{MAX}, T_A = T_{MIN} to T_{MAX}	90	100	110	Ω

ABSOLUTE MAXIMUM RATINGS

Table 3.

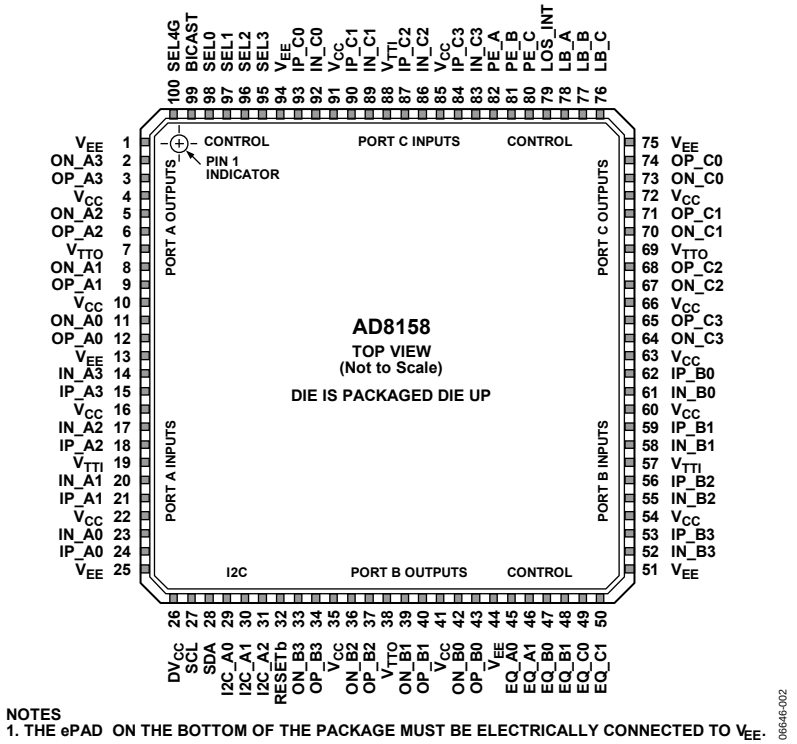
Parameter	Rating
V_{CC} to V_{EE}	3.7 V
DV_{CC} to V_{EE}	3.7 V
V_{TTI}	Lower of (V_{CC} + 0.6 V) or 3.6V
V_{TTO}	Lower of (V_{CC} + 0.6 V) or 3.6V
V_{CC} to DV_{CC}	0.6 V
Internal Power Dissipation	4.26 W
Differential Input Voltage	2.0 V
Logic Input Voltage	V_{EE} − 0.3 V < V_{IN} < V_{CC} + 0.6 V
Storage Temperature Range	−65°C to +125°C
Lead Temperature	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS



NOTES
1. THE ePAD ON THE BOTTOM OF THE PACKAGE MUST BE ELECTRICALLY CONNECTED TO V_{EE}.

THEORY OF OPERATION

The AD8158 is a buffered, asynchronous, three-port transceiver that allows 2:1 multiplexing and 1:2 demultiplexing among its ports. The 1:2 demux path supports bicast operation, allowing the AD8158 to operate as a port replicator as well as a redundancy switch. The AD8158 offers loopback on each lane, allowing the part to be configured as a 12-lane equalizer or redriver with FFE.

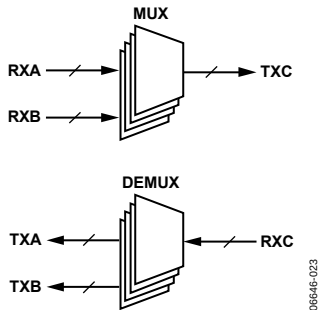

Figure 35. Mux/Demux Paths, Port A to Port C

The part offers extensively programmable transmit output levels and pre-emphasis settings as well as squelch or full-disable. The receivers integrate a programmable, multizero transfer function for aggressive equalization and a programmable loss-of-signal feature. The AD8158 provides a balanced, high speed switch core that maintains low lane-to-lane skew while preserving edge rates.

The I/O on-chip termination resistors are tied to user-settable supplies for increased flexibility. The AD8158 supports a wide primary supply range; V_{CC} can be set from 1.8 V to 3.3 V. These features, together with programmable transmitter output levels, allow for a wide range of dc- and ac-coupled I/O configurations.

The AD8158 supports several control and configuration modes, shown in Table 5.

Table 5. Control Modes

Mode	Description
Toggle Pin Control	Asynchronous control through toggle pins only
Mixed Control	Switch configuration via toggle pins, register-based control through the I²C serial interface
Serial Control	Register-based control through the I²C serial interface

The pin control mode offers access to a subset of the total feature list but allows for a much simplified control scheme. Table 6 compares the available features in all control modes.

The primary advantage of using the serial control interface is that it allows finer resolution in setting receive equalization, transmitter pre-emphasis, loss-of-signal (LOS) behavior, and output levels.

By default, the AD8158 starts in the pin control mode. Strobing the RESETb pin sets all on-chip registers to their default values and uses pins to configure switch connectivity, PE, and EQ levels. In mixed mode, switch connectivity is still controlled through the SEL[3:0], LB_[A:C], and BICAST pins. The user can override PE and EQ settings in mixed mode. In serial mode, all functions are accessed through registers and the control pin inputs are ignored, except RESETb. Register 0x0F selects the control mode (see Table 7).

The AD8158 register set is controlled through a 2-wire I²C interface. The AD8158 acts only as an I²C slave device. The 7-bit slave address for the AD8158 I²C interface contains the static value b1010 for the upper four bits. The lower three bits are controlled by the input pins I2C_A[2:0].

Table 6. Features Available Through Toggle Pin or Serial Control

Feature	Pin Control	Serial Control
Switch Features		
BICAST	One pin	One bit
A/B Lane Select	Four pins	Four bits
Loopback	Three pins	Three bits
Rx Features		
EQ Levels	Four settings	10 settings
N/P Swap	Not available	Available
Squelch	Enabled	Three bits
Tx Features		
Programmable Output Levels	±400 mV diff fixed[1]	±200 mV diff/±300 mV diff/±400 mV diff/±600 mV diff
PE Levels	Two settings	>7 settings

[1] ±400 mV diff indicates a 400 mV amplitude signal measured between two differential nodes. The voltage swing at differential I/O pins is described in this data sheet both in terms of the differentially measured voltage range (±400 mV diff, for example) and in terms of peak-to-peak differential swing, denoted mV p-p diff. An output level setting of ±400 mV diff delivers a differential peak-to-peak output voltage of 800 mV p-p diff.

Table 7. Register Address 0x0F

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Function
Set to 0	Set to 0	Set to 0	Set to 0	Set to 0	Set to 0	MODE[1]	MODE[0]	Mode

Table 8. Setting the Control Interface Mode

Mode 1	Mode 0	Control Mode
0	0	Pin control
0	1	Mixed control
1	1	Serial control

THE SWITCH (MUX/DEMUX/UNICAST/BICAST/LOOPBACK)

The mux and demux functions of the AD8158 can be controlled either with the toggle pins or through the register map. The multiplexer path switches received data from Input Port A or Input Port B to Output Port C. The SEL[3:0] pins allow switching lanes independently. The demultiplexer path switches received data from Input Port C to Output Port A, Output Port B, or (if bicast mode is enabled) to both Output Port A and Output Port B.

Table 9. Port Selection and Configuration with All Loopbacks Disabled

BICAST	SELx	Output Port A	Output Port B	Output Port C
0	0	Ix_C[3:0]	Idle	Ix_A[3:0]
0	1	Idle	Ix_C[3:0]	Ix_B[3:0]
1	0	Ix_C[3:0]	Ix_C[3:0]	Ix_A[3:0]
1	1	Ix_C[3:0]	Ix_C[3:0]	Ix_B[3:0]

When the device is in unicast mode, the output lanes on either Port A or Port B are in an idle state. In the idle state, the output tail current is set to 0, and the P and N sides of the lane are pulled up to the output termination voltage through the on-chip termination resistors. To save power, the unused receiver automatically disables.

The AD8158 supports port-level loopback, illustrated in Figure 36. The loopback control pins override the lane select (SEL[3:0]) and bicast control (BICAST) pin settings at the port level. In serial control mode, Bits [6:4] of Register 0x01 control loopback and are equivalent to asserting Pin LB_A, Pin LB_B, and Pin LB_C. Table 10 summarizes the different loopback configurations.

The loopback feature is useful for system debug, self test, and initialization, allowing system ASICs to compare Tx and Rx data sent over a single bidirectional link. Loopback can also be used to configure the device as a 4- to 12-lane receive equalizer or backplane redriver.

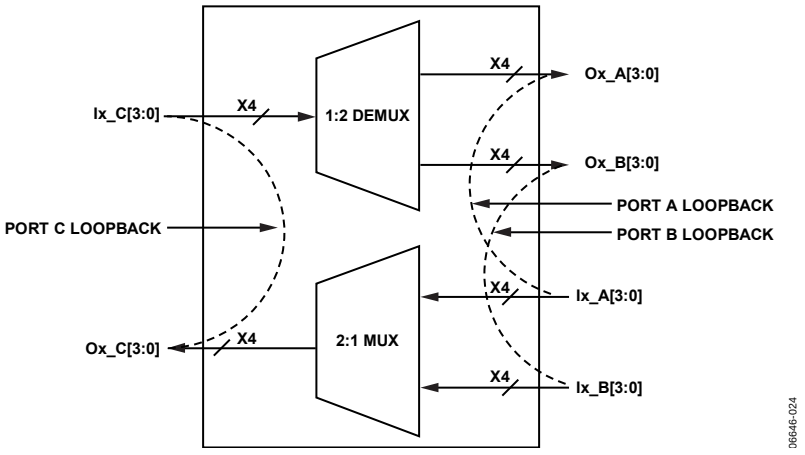

Figure 36. Port Level Loopback

Table 10. Switch Connectivity vs. Loopback, BICAST, and Port Select Settings

LBA	LBB	LBC	BICAST	SELAb/B	Output Port A	Output Port B	Output Port C

RECEIVERS

The AD8158 receivers incorporate 50 Ω on-chip termination, ESD protection, and a multizero equalization function capable of delivering up to 18 dB of boost at 4.25 GHz. The AD8158 can compensate signal degradation at 6.5 Gbps from over 40 inches of FR-4 backplane trace. The receive path also incorporates a loss-of-signal (LOS) function with user programmable threshold and hysteresis, which squelches the associated transmitter when the midband differential voltage falls below a specified threshold value. Finally, the receivers implement a sign-swapping option (P/N swap), which allows the user to invert the sign of the input signal path and eliminates the need for board-level crossovers in the receive channels.

Input Structure and Allowed Input Levels

The AD8158 tolerates an input common-mode range (measured with zero differential input) of

$$V_{EE} + 0.6\ V < V_{IN\_CM} < V_{CC} + 0.3\ V$$

Typical supply configurations include, but are not limited to, those listed in Table 11.

Table 11. Typical Input Supply Configurations

Configuration	DV_{CC}	V_{CC}	V_{TTI}
Low V_{TTI}, AC-Coupled Input	3.3 V – 1.8 V	1.8 V	1.6 V
Single 1.8 V Supply	3.3 V – 1.8 V	1.8 V	1.8 V
3.3 V Core	3.3 V	3.3 V	1.8 V
Single 3.3 V Supply	3.3 V	3.3 V	3.3 V

When dc-coupling with LVDS, CML, or ECL signals, it can be advantageous to operate with split or negative supplies (see the Applications Information section). In these applications, it is necessary to observe the maximum voltage ratings between V_{CC} and V_{EE} and generally to select supply voltages for V_{TTO} and V_{TTI} in the range of V_{CC} to V_{EE} to avoid activating the ESD protection devices.

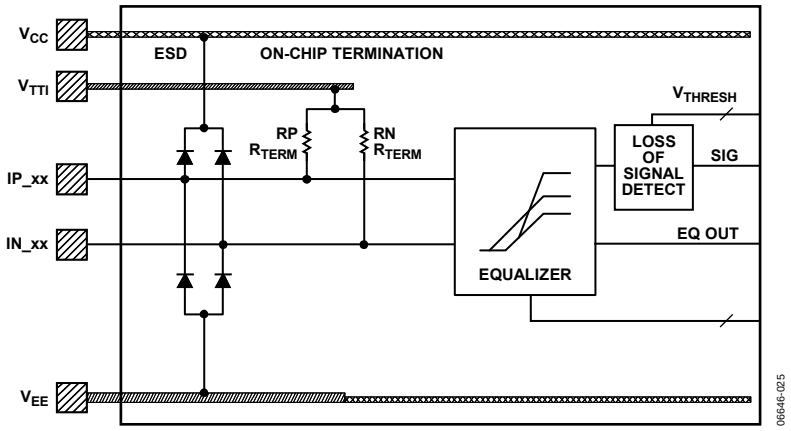

Figure 37. Functional Diagram of the AD8158 Receiver

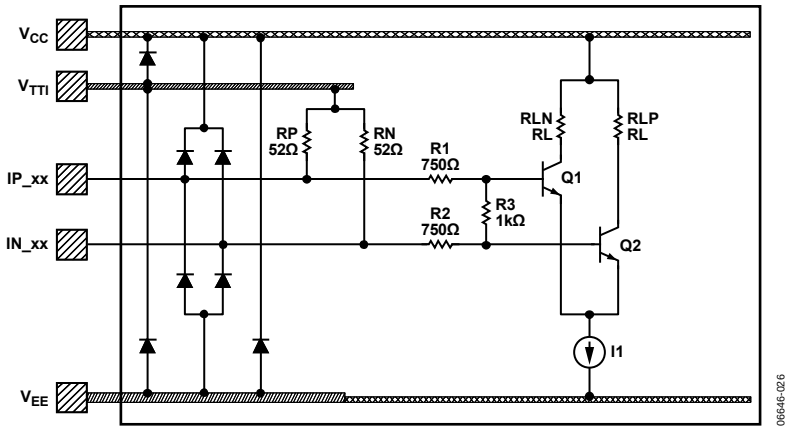

Figure 38. Simplified Receiver Input Structure

LANE DISABLES

By default, the receivers and transmitters enable in an on-demand fashion according to the state of the SEL[3:0], LB_[A:C], and BICAST pins or to the state of the equivalent registers in serial control mode. Register 0x40, Register 0x80, and Register 0xC0 implement per-lane disables for the receivers and Register 0x48, Register 0x88, and Register 0xC8 implement per-lane transmitter disables. These disables override the default settings. Each bit in the register is named for the lane and function it disables. For example, RXDIS B2 disables the receiver on Lane 2 of Port B while TXDIS C3 disables the Lane 3 transmitter of Port C (see Table 12).

EQUALIZER SETTINGS

Every input lane offers a low power, asynchronous, programmable receive equalizer for NRZ data up to 6.5 Gbps. The pin control interface makes four levels of receive equalization available: 6 dB, 12 dB, 15 dB, and 18 dB. Register-based control allows the user 10 equalizer settings within this range. High frequency boost increases monotonically (and approximately linearly) with EQ control setting in ~2 dB steps.

The four LSBs of Register 0x41, Register 0x81, and Register 0xC1 allow programming of all the equalizers in a port simultaneously (see Table 12). The 0x42, 0x43, 0x82, 0x83, 0xC2, and 0xC3 registers allow per-lane programming of the equalizers (see Table 23). Be aware that writing to the port-level equalizer registers updates and overwrites per-lane settings.

LOSS OF SIGNAL (LOS)

The serial control interface allows access to the AD8158 loss of signal features. (LOS is not available in pin control mode.) Each receiver includes a low power, loss-of-signal detector. The loss-of-signal circuit monitors the received data stream and generates a system interrupt when the received signal power falls below a programmed threshold. The default threshold is 25 mV diff, referred to the input pins. The LOS circuit monitors the equalized receive waveform and integrates the rms power of the equalized waveform over a selectable interval of either 2 ns or 10 ns. The detectors are enabled on a per-port basis with Bit 0 of the RXA/B/C LOS control registers (0x51, 0x91, 0xD1).

By default, when the receiver detects an LOS event, it squelches its associated transmitter, lowering the output current to submicroamps. This prevents the high gain, wide bandwidth signal path from turning low-level system noise on an undriven input pair into a source of hostile crosstalk at the transmitter. The squelch feature can be disabled with Bit 3 of the global squelch control register (0x04).

Register 0x50, Register 0x90, and Register 0xD0 set values for the LOS signal detection threshold for Port A, Port B, and Port C, respectively. The recommended setting is Rx LOS threshold register = 0x10 with Rx LOS control register = 0x05. This is an optimum setting that all parts are factory tested to comply with (see Table 1).

LOS Recommended Settings

Rx LOS threshold register: 0x10

Rx LOS control register: 0x05

Register 0x51, Register 0x91, and Register 0xD1 set the integration interval, LOS gain, and the enable state for the LOS feature for Port A, Port B, and Port C, respectively (see Table 14 through Table 16)

Bit 0, LOS_ENB, enables and disables the LOS detectors. (The default setting is enabled, LOS_ENB = 1).

Bit 1, LOS_GSEL, adjusts the detector gain (1 = high gain, 0 = low gain). A value of 0 is recommended.

Bit 2, LOS_FILT, adjusts the interval over which incoming data is averaged. LOS_FILT = 0 gives a 2 ns interval and LOS_FILT = 1 sets a 10 ns interval.

Bit 7 through Bit 3 should be set to 0.

Table 16. Loss-of-Signal Configuration Bits

Bit(s)	Function	Description	Default
THRBIT[5:0]	LOS threshold	Binary coded value between 0 and 31. Covers ranges of 10 mV to 60 mV and 60 mV to 250 mV for LOS_GSEL = 0 and LOS_GSEL = 1, respectively. Recommended setting = 0x10.	0x1C V_{IN_DC} < 50 mV
LOS_FILT	LOS filter	Loss-of-signal filter. 0: LOS integrates 2 ns of data. 1: LOS integrates 10 ns of data.	1
LOS_GSEL	LOS sensitivity	LOS gain select. Recommended setting = 0. 0: LOS covers an input range of 60 mV to 250 mV. 1: LOS covers an input range of 10 mV to 60 mV.	1
LOS_ENB	LOS enable	LOS enable. 0: LOS function disabled 1: LOS function enabled	1

The LOS_INT pin evaluates a logical OR of all LOS status register bits for all enabled receivers. (LOS status registers are located at 0x45, 0x85, and 0xC5.) The upper four bits in the RXA, RXB, and RXC LOS status registers are sticky while the four LSBs are continuously updated to indicate the instantaneous status of LOS for an enabled receiver. The sticky bits are cleared by writing 0 to the RXA, RXB, and RXC LOS status registers. The LOS_INT pin remains high after an LOS event until all sticky registers are cleared and all active status registers (for example, Bits [3:0]) read 0.

The LOS_INT pin can be used to generate an interrupt for the system control software. In a standard implementation, when LOS_INT goes high, the system software registers the interrupt and polls the RXA, RXB, and RXC LOS status registers to determine which input lost signal and if the signal has been restored.

LANE INVERSION: P/N SWAP

The receiver P/N swap function is a convenience intended to allow the user to implement the equivalent of a board-level routing crossover in a much smaller area while eliminating vias (impedance discontinuities) that compromise the high frequency integrity of the signal path.

A Note of Caution

Using this feature to correct an inversion downstream of the receiver may require the user to be aware of the sign of the data when switching connectivity (the mux/demux path). The feature is available on a per-lane setting through Register 0x44, Register 0x84, and Register 0xC4. Setting the bit true flips the sign sense of the P and N inputs for the associated lane. The default setting is 0 (no inversion).

TRANSMITTERS

The AD8158 transmitter offers programmable pre-emphasis, programmable output levels, output disable, and transmit squelch. The SEL4G pin lets the user lower the transmitter frequency of maximum boost from 3.25 GHz to 2.0 GHz, allowing the AD8158 to offer exceptional transmit channel compensation for legacy applications (4.5 Gbps and slower).

OUTPUT LEVEL PROGRAMMING AND OUTPUT STRUCTURE

The output level of the transmitter of each lane is independently programmable. In pin control mode, a default output amplitude of 800 mV p-p diff (±400 mV diff) is delivered (see Table 17). Register-based control allows the user to set the transmitter output levels on a per-port or per-lane basis to four predefined levels. Port-level programming overwrites lane-level configuration. The ALEV, BLEV, and CLEV bits in Register 0x49, Register 0x89, and Register 0xC9, respectively, are used to set the output levels for all transmitters. The A[3:0]OLEV[1:0], B[3:0]OLEV[1:0], and C[3:0]OLEV[1:0] bits in Register 0x4C, Register 0x8C, and Register 0xCC allow per-lane settings (see Table 23).

Table 17. Predefined Output Levels

[A/B/C]OLEV1	[A/B/C]OLEV0	Output Level
0	0	±200 mV diff
0	1	±300 mV diff
1	0	±400 mV diff (default)
1	1	± 600 mV diff

Note that the choice of output level influences the output common-mode level. A 600 mV diff output level with a full PE range requires a supply and output termination voltage of 2.5 V or higher (V_{TTO}, $V_{CC} \geq 2.5$ V).

PRE-EMPHASIS

Transmitter pre-emphasis levels can be set by pin control or through the control registers. Pin control allows two settings of PE, 0 dB, and 6 dB. The control registers provide seven levels of PE. Note that a larger range of boost settings is available for lower output levels.

Pre-emphasis can be programmed per-port or per-lane. Register 0x49, Register 0x89, and Register 0xC9 set all outputs in a port at once. Registers 0x4A, 0x4B, 0x8A, 0x8B, 0xCA, and 0xCB allow setting PE on a per-lane basis.

Table 18. Lane Inversion Bits

Address	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Function

OUTPUT COMPLIANCE, AC vs. DC COUPLING, MINIMUM SUPPLY VOLTAGE, AND THE TX_HEADROOM BIT

In low voltage applications, users must pay careful attention to both the differential and common-mode signal level. The choice of output voltage swing, pre-emphasis setting, supply voltages (V_{CC} and V_{TTO}), and output coupling (ac or dc) affect peak and settled single-ended voltage swings and the common-mode shift measured across the output termination resistors. These choices also affect output current and, consequently, power consumption.

Table 20 shows the change in output common-mode ($dV_{OCM} = V_{CC} - V_{OCM}$) with output level ($V_{OD}$) and pre-emphasis setting. Table 20 also shows the minimum and maximum dc and peak single-ended output levels (V_L, V_H, V_L peak, and V_H peak, respectively). The single-ended output levels are calculated for V_{TTO} supplies of 3.3 V and 1.8 V to illustrate practical challenges of reducing the supply voltage. Table 20 shows the voltage margins required for proper transmitter operation. Minimum V_L (min V_L) is the lowest single-ended voltage allowed given the user's choice of V_{CC} voltage.

For output levels greater than 400 mV diff (800 mV p-p diff), or when enabling the TX_HEADROOM bit, operating the part from core supply voltage, $V_{CC} \geq 2.5$ V, is suggested. In this high current case, setting the TX_HEADROOM bit to 1 allows the transmitter an extra 200 mV of output compliance range. Additional transmitter headroom is enabled on a per-port basis through Bits [6:4] in Register 0x05. A value of 0 disables the headroom generating circuitry; a value of 1 enables it.

Examples

Consider a typical application using pin control mode. In this case, the default output level of 400 mV diff (800 mV p-p diff) is selected and the user can choose pre-emphasis settings of 0 dB or 6 dB. Table 19 shows that with pre-emphasis disabled, a dc-coupled transmitter causes a 200 mV common-mode shift across the termination resistors whereas an ac-coupled transmitter causes twice the common-mode shift. Notice that with V_{CC} and V_{TTO} powered from a 1.8 V supply, the single-ended output voltage swings between 1.8 V and 1.4 V when dc-coupled and between 1.6 V and 1.2 V when ac-coupled. (Note also that $V_H = V_H$ peak and $V_L = V_L$ peak because transmitter pre-emphasis is disabled.) In both cases, these levels are greater than the minimum V_L limit of 725 mV, and V_{CC} satisfies the minimum V_{CC} limit of 1.8 V with the TX_HEADROOM bit set to 0. Note that setting TX_HEADROOM = 1 violates the minimum V_{CC} limit of 2.5 V.

With a PE setting of 6.02 dB, the ac-coupled transmitter has single-ended swings from 1.4 V to 0.6 V while the dc-coupled transmitter outputs swing between 1.8 V and 1 V. The peak minimum single-ended swing (V_L peak) of the ac-coupled transmitter, in this case, exceeds the minimum V_L limit of 725 mV by 125 mV. While objectionable in theory, in practice, this setting works quite well. The transmitter theoretical peak voltage is rarely achieved in practice because the high frequency characteristic of the pre-emphasis is attenuated at the output pins by the low-pass nature of the PC board environment and the channel. For 6.5 Gbps PE (SEL4G = 0), a 30% reduction of overshoot is not unexpected. For an output level of 400 mV diff and a PE setting of 6 dB, the user can calculate a maximum overshoot of 400 mV diff but can measure only a 270 mV overshoot.

Theory (maximum)

$$V\_overshoot\_max = V_{OD} \times (PE\ [\text{V/V}] - 1)$$

Measured

$$V\_overshoot\_measured = V_{OD} \times (PE\ [\text{V/V}] - 1) \times (1 - 0.3)$$

With the pre-emphasis configured for 4.25 Gbps operation (SEL4G = 1), the overshoot can only be reduced 5% from the theoretic maximum. In this case, the peak minimum voltage limit should be more closely observed.

SIGNAL LEVELS AND COMMON-MODE SHIFT FOR AC-COUPLED AND DC-COUPLED OUTPUTS

Table 20. Output Voltage Range and Output Common-Mode Shift vs. Output Level and PE Setting

Table 21. Symbol Definitions

Symbol	Formula	Definition
V_{OD}	$25\ \Omega \times I_{DC}$	Peak differential output voltage
V_{OD} p-p	$25\ \Omega \times I_{DC} \times 2 = 2 \times V_{OD}$	Peak-to-peak differential output voltage
$\Delta V_{OCM\_DC\text{-}COUPLED}$	$25\ \Omega \times I_{TX}/2 = V_{ODPP}/4 + (I_{PE}/2 \times 25)$	Output common-mode shift
$\Delta V_{OCM\_AC\text{-}COUPLED}$	$50\ \Omega \times I_{TX}/2 = V_{ODPP}/2 + (I_{PE}/2 \times 50)$	Output common-mode shift
I_{DC}	V_{OD}/R_{TERM}	Output current that sets output level
I_{PE}	N/A	Output current used for PE
I_{TX}	$I_{DC} + I_{PE}$	Total transmitter output current
V_H	$V_{TTO} - \Delta V_{OCM} + V_{OD}/2$	Maximum single-ended output voltage
V_L	$V_{TTO} - \Delta V_{OCM} - V_{OD}/2$	Minimum single-ended output voltage

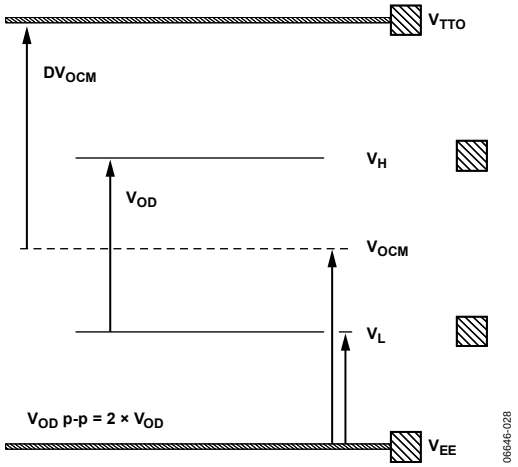

Figure 40. V_H, V_L, V_{OCM}

SQUELCH AND DISABLE

Each transmitter is equipped with disable and squelch controls. Disable is a full power-down state: the transmitter current is reduced to zero and the output pins pull up to V_{TTO}, but there is a delay of approximately 1 µs associated with re-enabling the transmitter. Squelch simply reduces the output current to submicroamp levels, again allowing both output pins to pull up to V_{TTO} through the output termination resistors. The transmitter recovers from squelch in less than 100 ns.

SPEED SELECT

The SEL4G pin lets the user lower the transmitter frequency of maximum boost from 3.25 GHz to 2.0 GHz, allowing the AD8158 to offer exceptional transmit channel compensation for legacy applications (4.5 Gbps and slower). SEL4G = 1 lowers the frequency of maximum boost without sacrificing the amount of boost delivered.

AD8158 POWER CONSUMPTION

There are several sections of the AD8158 that draw varying power depending on the supply voltages, the type of I/O coupling used, and the status of the AD8158 operation. Figure 41 shows a block diagram of these sections. Figure 42 summarizes the power consumption of each section and is a useful guide as the following sections are reviewed.

A power budget calculator is available on the AD8158 product page at www.analog.com.

Figure 42. Power Budget Calculator

The first section is the input termination resistors. The power dissipated in the termination resistors is due to the input differential swing and any common-mode current resulting from dc-coupling the input.

In the next section, the receiver, each input is powered only when it is selected and the disable bits are set to 0. If a receiver is not selected, it is powered down. Thus, the total number of active inputs affects the total power consumption. Furthermore, the loss-of-signal detection circuits can be disabled independent of the receiver for even greater power savings.

The core of the device performs the multiplexer and demultiplexer switching functions. It draws a fixed quiescent current of 2 mA whenever the AD8158 is powered from V_{CC} to V_{EE}. The switch draws an additional 8 × 4.6 mA in normal mux/demux operation and an additional 12 × 4.6 mA with all ports in loopback or with bicast selected. The switch core can be disabled to save power.

An output predriver section draws a current, I_{PRED}, that is related to the programmed output current, I_{TOT}. Table 20 lists values for I_{TOT} and I_{PRED} for all settings of output level and pre-emphasis. The predriver current always flows from V_{CC} to V_{EE}. It is treated separately from the output current, which flows from V_{TTO}, and may not be the same voltage as V_{CC}.

The final section is the outputs. For an individual output, the programmed output current flows through two separate paths. One is the on-chip termination resistor, and the other is the transmission line and the destination termination resistor. The nominal parallel impedance of these two paths is 25 Ω. The sum of these two currents flows through the switches and the current source of the AD8158 output circuit and out through V_{EE}. The power dissipated in the transmission line and the destination resistor is not dissipated in the AD8158 but has to be supplied from the power supply and is a factor in the overall system power. The current in the on-chip termination resistors and the output current source dissipate power in the AD8158 itself.

OUTPUTS

The output current is set by a combination of output level and pre-emphasis setting (see Table 20). For the two logic switch states, this current flows through an on-chip termination resistor and a parallel path to the destination device and its termination resistor. The power in this parallel path is not dissipated by the AD8158. With pre-emphasis enabled, some current always flows in both the P and N termination resistors. This pre-emphasis current gives rise to an output common-mode shift, which varies with ac-coupling or dc-coupling and which is calculated for both cases in Table 20.

Perhaps the most direct method for calculating power dissipated in the output is to calculate the power that would be dissipated if all of I_{TOT} were to flow on-die from V_{TTO} to V_{EE} and to subtract from this the power dissipated off-die in the destination device termination resistors and the channel. For this purpose, the destination device and channel can be modeled as 50 Ω load resistors, R_L, in parallel with the AD8158 termination resistors.

POWER SAVING CONSIDERATIONS

While the AD8158 power consumption is very low compared to similar devices, careful control of its operating conditions can yield further power savings. Significant power reduction can be realized by operating the part at a lower voltage. Compared to 3.3 V operation, a supply voltage of 1.8 V can result in power savings of ~45%. There is no performance penalty when operating at lower voltage.

A second measure is to disable transmitters when they are not being used. This can be done on a static basis if the output is not used or on a dynamic basis if the output does not have a constant stream of traffic. On transmit disable (Register 0x48, Register 0x88, Register 0xC8), both the predriver and output switch currents are disabled. The LOS-activated squelch disables only the output switch current, I_{TOT}. Superior power saving is achieved by using the TX and RX disable registers to turn off an unused lane as opposed to relying on the AD8158 transmit squelch feature.

Because the majority of the power dissipated is in the output stage, some of its flexibility can be used to lower the power consumption. First, the output current and output pre-emphasis settings can be programmed to the smallest amount required to maintain BER performance. If an output circuit always has a short length and the receiver has good sensitivity, then a lower output current can be used.

It is also possible to lower the voltage on V_{TTO} to lower the power dissipation. The amount that V_{TTO} can be lowered is dependent on the lowest of all the output's V_{OL} and V_{CC}. This is determined by the output that is operating at the highest programmed output current. Table 1 and Table 20 list minimum output levels.

I²C CONTROL INTERFACE

SERIAL INTERFACE GENERAL FUNCTIONALITY

The AD8158 register set is controlled through a 2-wire I²C interface. The AD8158 acts only as an I²C slave device. The 7-bit slave address for the AD8158 I2C interface contains the static value b1010 for the upper four bits. The lower three bits are controlled by the input pins I2C_A[2:0].

Therefore, the I²C bus in the system needs to include an I²C master to configure the AD8158 and other I²C devices that may be on the bus. Data transfers are controlled through the use of the two I²C wires: the SCL input clock pin and the SDA bidirectional data pin.

The AD8158 I²C interface can be run in the standard (100 kHz) and fast (400 kHz) modes. The SDA line only changes value when the SCL pin is low with two exceptions. To indicate the beginning or continuation of a transfer, the SDA pin is driven low while the SCL pin is high, and to indicate the end of a transfer, the SDA line is driven high while the SCL line is high. Therefore, it is important to control the SCL clock to toggle only when the SDA line is stable unless indicating a start, repeated start, or stop condition.

I²C INTERFACE DATA TRANSFERS: DATA WRITE

To write data to the AD8158 register set, a microcontroller or any other I²C master needs to send the appropriate control signals to the AD8158 slave device. The following steps need to be taken, where the signals are controlled by the I²C master, unless otherwise specified. For a diagram of the procedure, see Figure 43.

1. Send a start condition (while holding the SCL line high, pull the SDA line low).
2. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A[2:0] input pins. This transfer should be MSB first.
3. Send the write indicator bit (0).
4. Wait for the AD8158 to acknowledge the request.
5. Send the register address (eight bits) to which data is to be written. This transfer should be MSB first.
6. Wait for the AD8158 to acknowledge the request.
7. Send the data (eight bits) to be written to the register whose address was set in Step 5. This transfer should be MSB first.
8. Wait for the AD8158 to acknowledge the request.

9a. Send a stop condition (while holding the SCL line high, pull the SDA line high) and release control of the bus.

9b. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 in this procedure to perform another write.

9c. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of the read procedure (in the I2C Interface Data Transfers: Data Read section) to perform a read from another address.

9d. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 8 of the read procedure (in the I2C Interface Data Transfers: Data Read section) to perform a read from the same address set in Step 5.

In Figure 43, the AD8158 write process is shown. The SCL signal is shown along with a general write operation and a specific example. In this example, the value 0x92 is written to Address 0x6D of an AD8158 device with a part address of 0x53. The part address is seven bits wide and is composed of the AD8158 static upper four bits (b1010) and the pin-programmable lower three bits (I2C_A[2:0]). The address pins are set to b011. In Figure 43, the corresponding step number is visible in the circle under the waveform. The SCL line is driven by the I²C master and never by the AD8158 slave. As for the SDA line, the data in the shaded polygons is driven by the AD8158, whereas the data in the nonshaded polygons is driven by the I²C master. The end phase case shown is that of Step 9A.

It is important to note that the SDA line only changes when the SCL line is low, except for the case of sending a start, stop, or repeated start condition (Step 1 and Step 9 in this case).

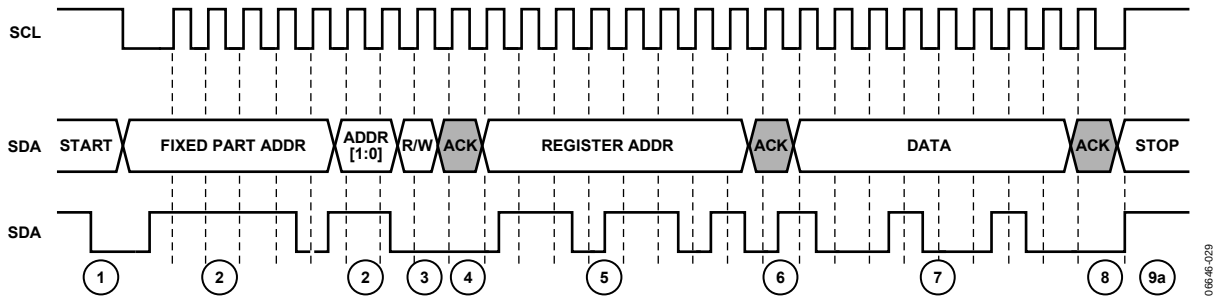

Figure 43. I²C Write Diagram

I²C INTERFACE DATA TRANSFERS: DATA READ

To read data from the AD8158 register set, a microcontroller or any other I²C master needs to send the appropriate control signals to the AD8158 slave device. The following steps need to be taken, where the signals are controlled by the I²C master, unless otherwise specified. For a diagram of the procedure, see Figure 44.

1. Send a start condition (while holding the SCL line high, pull the SDA line low).
2. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A[2:0] input pins. This transfer should be MSB first.
3. Send the write indicator bit (0).
4. Wait for the AD8158 to acknowledge the request.
5. Send the register address (eight bits) from which data is to be read. This transfer should be MSB first. The register address is kept in memory in the AD8158 until the part is reset or the register address is written over with the same procedure (Step 1 to Step 6).
6. Wait for the AD8158 to acknowledge the request.
7. Send a repeated start condition (while holding the SCL line high, pull the SDA line low).
8. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A[2:0] input pins. This transfer should be MSB first.
9. Send the read indicator bit (1).
10. Wait for the AD8158 to acknowledge the request.
11. The AD8158 then serially transfers the data (eight bits) held in the register indicated by the address set in Step 5.
12. Acknowledge the data.

13a. Send a stop condition (while holding the SCL line high, pull the SDA line high) and release control of the bus.
13b. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of the write procedure (see the I2C Interface Data Transfers: Data Write section) to perform a write.
13c. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of this procedure to perform a read from another address.
13d. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 8 of this procedure to perform a read from the same address.

In Figure 44, the AD8158 read process is shown. The SCL signal is shown along with a general read operation and a specific example. In this example, the value 0x49 is read from Address 0x6D of an AD8158 device with a 0x53 part address. The part address is seven bits wide and is composed of the AD8158 static upper four bits (b1010) and the pin-programmable lower three bits (I2C_A[2:0]). The address pins are set to b011. In Figure 44, the corresponding step number is visible in the circle under the waveform. The SCL line is driven by the I²C master and never by the AD8158 slave. As for the SDA line, the data in the shaded polygons is driven by the AD8158, whereas the data in the nonshaded polygons is driven by the I²C master. The end phase case shown is that of Step 13A.

It is important to note that the SDA line only changes when the SCL line is low, except for the case of sending a start, stop, or repeated start condition, as in Step 1, Step 7, and Step 13. In Figure 44, A is the same as ACK. Equally, Sr represents a repeated start where the SDA line is brought high before SCL is raised. SDA is then dropped while SCL is still high.

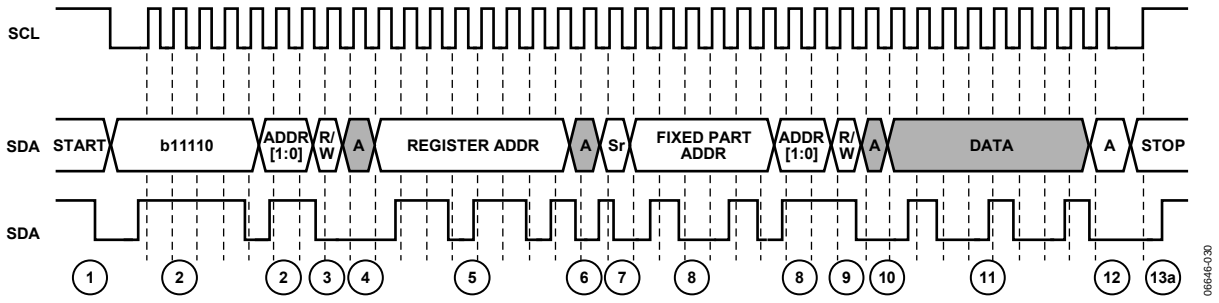

Figure 44. I²C Read Diagram

APPLICATIONS INFORMATION

SUPPLY SEQUENCING

Ideally, all power supplies should be brought up to the appropriate levels simultaneously (power supply requirements are set by the supply limits in Table 1 and the absolute maximum ratings listed in Table 3). In the event that the power supplies to the AD8158 are brought up separately, the supply power-up sequence is as follows: DV_{CC} powered first, followed by V_{CC}, and lastly V_{TTI} and V_{TTO}. The power-down sequence is reversed with V_{TTI} and V_{TTO} being powered off first.

V_{TTI} and V_{TTO} contain ESD protection diodes to the V_{CC} power domain (see Figure 38 and Figure 39). To avoid a sustained high current condition in these devices ($I_{SUSTAINED}$ < 100 mA), the V_{TTI} and V_{TTO} supplies should be powered on after V_{CC} and should be powered off before V_{CC}.

If the system power supplies have a high impedance in the powered off state, then supply sequencing is not required provided the following limits are observed:

- Peak current from V_{TTI} or V_{TTO} to V_{CC} < 200 mA
- Sustained current from V_{TTI} or V_{TTO} to V_{CC} < 100 mA

SINGLE SUPPLY vs. MULTIPLE SUPPLY OPERATION

The AD8158 supports a flexible supply voltage of 1.8 V to 3.3 V. For some dc-coupled links, 1.2 V or ground-referenced signaling may be desired. In these cases, the AD8158 can be run with a split supply configuration.

Table 22. Alternate Supply Configuration Examples

Signal Level	V_{CC}, V_{TTI}, V_{TTO}	V_{EE}
1.2 V CML	1.2 V	−2.1 V ≤ V_{EE} ≤ −0.6 V
GND − 400 mV diff	GND	−3.3 V ≤ V_{EE} ≤ +1.8 V

The AD8158 control signals are always referenced between DV_{CC} and V_{EE} and, when using a split supply configuration, logic level-shift circuits should be used. The evaluation board design shows the use of the Analog Devices, Inc., ADUM1250 I^2C isolator and a level shifter to level-shift the SCL and SDA signals.

Evaluation of DC-Coupled Links

When evaluating the AD8158 dc-coupled, remember that most lab equipment is ground referenced while the AD8158 high speed I/O are connected by 50 Ω on-die termination resistors to V_{TTI} and V_{TTO}. To interface the AD8158 to ground-referenced, high speed instrumentation (for example, the 50 Ω inputs of a high speed oscilloscope), it is necessary to level-shift the outputs by either using a dc-blocking network or by powering the AD8158 between ground and a negative supply.

For example, to evaluate 1.8 V dc-coupled transmitter performance with a 50 Ω ground-referenced oscilloscope, use the following supply configuration:

$V_{CC} = V_{TTO} = V_{TTI} = Ground$

$V_{EE} = -1.8$ V

$Ground < DVCC < 1.5$ V

REGISTER MAP

All registers are port-level and global registers, unless otherwise noted.

Table 23. Register Definitions

Mnemonic	Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Default
