# 2.2MHz, Dual-Output Buck or Boost 

 Converter with POR and Power-Fail Output
## General Description

The MAX5072 is a dual-output DC-DC converter with integrated high-side n-channel power MOSFETs. Each output can be configured either as a buck converter or a boost converter. The MAX5072 is designed to manage the power requirements of $x$ DSL modems. The wide 5.5 V to 23 V input voltage range allows for the use of inexpensive AC adapters to power the device in xDSL modem applications. Each output is programmable down to 0.8 V in the buck mode and up to 28 V in the boost mode with an output voltage accuracy of $\pm 1 \%$. In the buck mode, converter 1 and converter 2 can deliver 2 A and 1A, respectively. The output switching frequency of each converter can be programmed from 200 kHz to 2.2 MHz to avoid harmonics in the xDSL frequency band of operation. Each output operates $180^{\circ}$ out-of-phase, thus reducing input-capacitor ripple current, size, and cost. A SYNC input facilitates external frequency synchronization. Moreover, a CLKOUT output provides out-of-phase clock signal with respect to converter 2, allowing four-phase operation using two MAX5072 ICs in master-slave configuration.
The MAX5072 includes an internal digital soft-start that reduces inrush current, eliminates output-voltage overshoot, and ensures monotonic rise in output voltage during power-up. The device includes a power-good output and power-on reset as well as manual reset. In addition, each converter output can be shut down individually. The MAX5072 features a "dying gasp" output, which goes low when the input voltage drops below a preprogrammed voltage. Protection features include output short-circuit protection for buck mode and maximum duty-cycle limit for boost operation, as well as thermal shutdown.
The MAX5072 is available in a thermally enhanced 32-pin thin QFN package that can dissipate 2.7 W at $+70^{\circ} \mathrm{C}$ ambient temperature. The device is rated for operation over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ extended, or $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ automotive temperature range.

Applications
xDSL Modems
xDSL Routers
Point-of-Load DC-DC Converters
Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE | PKG <br> CODE |
| :---: | :---: | :--- | :---: |
| MAX5072ETJ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 32 Thin QFN-EP* <br> $(5 \mathrm{~mm} \times 5 \mathrm{~mm})$ | T3255-4 |

*EP = Exposed pad.
Ordering Information continued at end of data sheet.

Features
-4.5V to 5.5 V or 5.5 V to 23 V Input Supply Voltage Range

- 0.8V (Buck) to 28V (Boost) Output Voltage
- Two Independent Output DC-DC Converters with Internal Power MOSFETs
- Each Output can be Configured in Buck or Boost Mode
- IOUT1 and IOUT2 of 2A and 1A (Respectively) in Buck Mode
- $180^{\circ}$ Out-of-Phase Operation
- Clock Output for Four-Phase Operation
- Switching Frequency Programmable from 200kHz to 2.2 MHz
- Digital Soft-Start and Independent Converter Shutdown
- SYNC Input, Power-On Reset, Manual Reset, And Power-Fail Output
- Short-Circuit Protection (Buck)/Maximum DutyCycle Limit (Boost)
- Thermal Shutdown
- Thermally Enhanced 32-Pin Thin QFN Package Dissipates up to 2.7 W at $+70^{\circ} \mathrm{C}$

Pin Configuration

Lead Temperature (soldering, 10s)
$+300^{\circ} \mathrm{C}$
*As per JEDEC51 standard.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | CLKOUT | Clock Output. CLKOUT is $45^{\circ}$ phase-shifted with respect to converter 2 (SOURCE2, Figure 3). Connect CLKOUT (master) to the SYNC of a second MAX5072 (slave) for a four-phase converter. |
| 2 | BST2/VDD2 | Buck Converter Operation-Bootstrap Flying-Capacitor Connection for Converter 2. Connect BST2/VDD2 to an external ceramic capacitor and diode according to the Standard Application Circuit (Figure 1). Boost Converter Operation-Driver Bypass Capacitor Connection. Connect a low-ESR $0.1 \mu \mathrm{~F}$ ceramic capacitor from BST2/VDD2 to PGND (Figure 9). |
| 3, 4 | DRAIN2 | Connection to Converter 2 Internal MOSFET Drain. Buck converter operation-use the MOSFET as a high-side switch and connect DRAIN2 to the input supply. Boost converter operation—use the MOSFET as a low-side switch and connect DRAIN2 to the inductor and diode junction (Figure 9). |
| 5 | EN2 | Active-High Enable Input for Converter 2. Drive EN2 low to shut down converter 2, drive EN2 high for normal operation. Use EN2 in conjunction with EN1 for supply sequencing. Connect to VL for always-on operation. |
| 6 | FB2 | Feedback Input for Converter 2. Connect FB2 to a resistive divider between converter 2's output and SGND to adjust the output voltage. To set the output voltage below 0.8 V , connect FB2 to a resistive voltage-divider from BYPASS to regulator 2's output (Figure 6). See the Setting the Output Voltage section. |
| 7 | COMP2 | Compensation Connection for Converter 2. See the Compensation section to compensate converter 2's control loop. |
| 8 | PFO | Dying Gasp Comparator Output. The PFO open-drain output goes low when PFI falls below the 0.78 V reference. |
| 9 | SYNC | External Clock Synchronization Input. Connect SYNC to a 400 kHz to 4400 kHz clock to synchronize the switching frequency with the system clock. Each converter frequency is one half the frequency applied to SYNC. Connect SYNC to SGND when not used. |
| 10 | PFI | Dying Gasp Comparator Noninverting Input. Connect a resistor-divider from the input supply to PFI. PFI forces PFO low when VPFI falls below 0.78 V . The PFI comparator has a 20 mV (typ) hysteresis. This is an uncommitted comparator and can be used for any protection feature such as OVP or POWER-GOOD. |

Figure 1. MAX5072 Dual Buck Regulator Application Circuit

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

## Detailed Description

## PWM Controller

The MAX5072 converter uses a pulse-width modulation (PWM) voltage-mode control scheme for each out-ofphase controller. It is nonsynchronous rectification and uses an external low-forward-drop Schottky diode for rectification. The controller generates the clock signal by dividing down the internal oscillator or the SYNC input when driven by an external clock, so each controller's switching frequency equals half the oscillator frequency (fsw = fosc / 2). An internal transconductance error amplifier produces an integrated error voltage at the COMP pin, providing high DC accuracy. The voltage at COMP sets the duty cycle using a PWM comparator and a ramp generator. At each rising edge of the clock, converter 1's high-side n-channel MOSFET turns on and remains on until either the appropriate or maximum duty cycle is reached, or the maximum current limit for the switch is detected. Converter 2 operates out-of-phase, so the second high-side MOSFET turns on at each falling edge of the clock.
In the case of buck operation (Figure 1), during each high-side MOSFET's on-time, the associated inductor current ramps up. During the second half of the switching cycle, the high-side MOSFET turns off and forward biases the Schottky rectifier. During this time, the SOURCE voltage is clamped to 0.4 V ( $\mathrm{VD}_{\mathrm{D}}$ ) below ground. The inductor releases the stored energy as its current ramps down, and provides current to the output. The bootstrap capacitor is also recharged from the inductance energy when the MOSFET turns off. The circuit goes in discontinuous conduction mode operation at light load, when the inductor current completely discharges before the next cycle commences. Under overload conditions, when the inductor current exceeds the peak current limit of the respective switch, the highside MOSFET turns off quickly and waits until the next clock cycle.
In the case of boost operation, the MOSFET is a lowside switch (Figure 9). During each on-time, the inductor current ramps up. During the second half of the switching cycle, the low-side switch turns off and forward biases the Schottky diode. During this time the DRAIN voltage is clamped to 0.4 V ( $\mathrm{V}_{\mathrm{D}}$ ) above Vout_ and the inductor provides energy to the output as well as replenishes the output capacitor charge.

## Internal Oscillator/Out-of-Phase Operation

The internal oscillator generates the $180^{\circ}$ out-of-phase clock signal required by each regulator. The internal oscillator frequency is programmable from 400 kHz to 4.4MHz using a single $1 \%$ resistor at Rosc. Use the following equation to calculate Rosc:

$$
\mathrm{R}_{\text {OSC }}=\frac{25 \times 10^{9}}{\mathrm{f}_{\text {OSC }}}
$$

where fosc is the internal oscillator frequency in hertz and ROSC in ohms.
The two independent regulators in the MAX5072 switch $180^{\circ}$ out-of-phase to reduce input filtering requirements, to reduce electromagnetic interference (EMI), and to improve efficiency. This effectively lowers component cost and saves board space, making the MAX5072 ideal for cost-sensitive applications.
With dual synchronized out-of-phase operation, the MAX5072's high-side MOSFETs turn on $180^{\circ}$ out-ofphase. The instantaneous input current peaks of both regulators do not overlap, resulting in reduced RMS ripple current and input voltage ripple. This reduces the required input capacitor ripple current rating, allows for fewer or less expensive capacitors, and reduces shielding requirements for EMI. The out-of-phase waveforms in the Typical Operating Characteristics demonstrate synchronized $180^{\circ}$ out-of-phase operation.

## Synchronization (SYNC)/Clock Output (CLKOUT)

The main oscillator can be synchronized to the system clock by applying an external clock (fsync) at SYNC. The fSYNC frequency must be twice the required operating frequency of an individual converter. Use a TTL logic signal for the external clock with at least a 100ns pulse width. Rosc is still required when using external synchronization. Program the internal oscillator frequency so 0.2 fSYNC < fosc $<1.2 \mathrm{fSYnc}$. The rising edge of fsYnc synchronizes the turn-on edge of internal MOSFET (see Figure 3).

$$
\mathrm{R}_{\text {OSC }}=\frac{25 \times 10^{9}}{\mathrm{f}_{\text {OSC }}}
$$

where fosc is the internal oscillator frequency in hertz and Rosc in ohms, fosc $=2 \times$ fsw.
Two MAX5072s can be connected in master-slave configuration for four ripple-phase operation. The MAX5072 provides a clock output (CLKOUT) that is $45^{\circ}$ phaseshifted with respect to the internal switch turn-on edge. Feed the CLKOUT of the master to the SYNC input of the slave. The effective input ripple switching frequency shall be four times the individual converter's switching frequency. When driving the master converter using external clock at SYNC, set the clock duty cycle to $50 \%$ for a $90^{\circ}$ phase-shifted operation.

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

Figure 2. Functional Diagram

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

Figure 3. Synchronized Controllers

Frequency Select (FSEL1)
Sometimes it is necessary to operate the converter at a lower switching frequency to keep the losses low for lower power dissipation. However, it is not possible to have different frequencies for two converters operating out-of-phase. Also, frequency beating may occur if the individual converter frequencies are not selected carefully. To avoid these issues, and still achieve the lower
power dissipation in the package, the MAX5072 provides a frequency select (FSEL1) pin. Connecting FSEL1 to ground reduces the switching frequency of converter 1 to $1 / 2$ the switching frequency of converter 2 and $1 / 4$ th of the internal oscillator switching frequency. In this case, the input capacitor ripple frequency is 1.5 times the converter 2 switching frequency and also has unsymmetrical ripple waveform.

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

## Input Voltage (V+)/Internal Linear Regulator (VL)

All internal control circuitry operates from an internally regulated nominal voltage of $5.2 \mathrm{~V}(\mathrm{VL})$. At higher input voltages $(\mathrm{V}+)$ of 5.5 V to 23 V , VL is regulated to 5.2 V . At 5.5 V or below, the internal linear regulator operates in dropout mode, where VL follows V+. Depending on the load on VL, the dropout voltage can be high enough to reduce VL below the undervoltage lockout (UVLO) threshold.

For input voltages of less than 5.5 V , connect $\mathrm{V}+$ and VL together. The load on VL is proportional to the switching frequency of converter 1 and converter 2 . See the VL Dropout Voltage vs. Each Converter Switching Frequency graph in the Typical Operating Characteristics. For input voltage ranges higher than 5.5 V , use the internal regulator.

Bypass V+ to SGND with a low-ESR, $0.1 \mu \mathrm{~F}$ or greater ceramic capacitor placed close to the MAX5072. Current spikes from VL may disturb internal circuitry powered by VL. Bypass VL with a low-ESR, ceramic $0.1 \mu \mathrm{~F}$ capacitor to PGND and a $4.7 \mu \mathrm{~F}$ capacitor to SGND.

## Undervoltage Lockout/Soft-Start

The MAX5072 includes an undervoltage lockout with hysteresis and a power-on-reset circuit for smooth converter turn-on and monotonic rise of the output voltage. The rising UVLO threshold is internally set to 4.3 V with a 175 mV hysteresis. Hysteresis at UVLO eliminates "chattering" during startup. When VL drops below UVLO, the internal switches are turned off and $\overline{\mathrm{RST}}$ is forced low.
Digital soft-start/soft-stop is provided internally to reduce input surge currents and glitches at the input during turn-on/turn-off. When UVLO is cleared and EN_ is high, digital soft-start slowly ramps up the internal reference voltage in 64 steps. The total soft-start period is 2048 switching cycles of the internal oscillator.
To calculate the soft-start period, use the following equation:

$$
\mathrm{tsS}_{\mathrm{S}}=\frac{2048}{\mathrm{f}_{\mathrm{OSC}}}
$$

where fOSC is the internal oscillator frequency in hertz, which is twice the switching frequency of each converter.

#### Abstract

Enable The MAX5072 dual converter provides separate enable inputs EN1 and EN2 to individually control or sequence the output voltages. These active-high enable inputs are TTL compatible. Pulling EN_ high ramps up the reference slowly, which provides soft-start at the outputs. Forcing the EN_ low externally disables the individual output and generates a RST signal. Use EN1, EN2, and PGOOD1 for sequencing (see Figure 4). Connect PGOOD1 to EN2 to make sure converter 1's output is within regulation before

 converter 2 starts. Add an RC network from VL to EN1 and EN2 to delay the individual converter. A larger RC time constant means a more delayed output. Sequencing reduces input inrush current and possible chattering. Connect the EN_ to VL for always-on operation.$\overline{M R}$
Microprocessor-based products require manual reset capability, allowing the operator or external logic circuitry to initiate a reset. A logic low on $\overline{M R}$ asserts reset. Reset remains asserted while MR is low, and for the Reset Active Timeout Period (tRP) after $\overline{\mathrm{MR}}$ returns high. $\overline{\mathrm{MR}}$ has an internal $44 \mathrm{k} \Omega$ pullup resistor to VL , so it can be left unconnected if not used. MR can be driven to TTL logic levels.
Connect a normally open momentary switch from $\overline{\mathrm{MR}}$ to SGND to create a manual reset function. Note that external debounce circuitry is not required. If $\overline{\mathrm{MR}}$ is driven from long cables or if the device is used in a noisy environment, connect a $0.1 \mu \mathrm{~F}$ capacitor from $\overline{\mathrm{MR}}$ to SGND to provide additional noise immunity.
$\overline{\mathrm{RST}}$ is an open-drain output. $\overline{\mathrm{RST}}$ pulls low when either
$\overline{\mathrm{RST}}$ is an open-drain output. $\overline{\text { RST pulls low when either }}$ output falls below 92.5\% of its nominal regulation voltage. Once both outputs exceed $92.5 \%$ of their nominal regulated voltages and both soft-start cycles are completed, $\overline{\text { RST }}$ enters a high-impedance state after the 180ms active timeout period. To obtain a logic-voltage output, connect a pullup resistor from $\overline{R S T}$ to a logic supply voltage. The internal open-drain MOSFET can supply voltage. The internal open-drain MOSFET can
sink 3 mA while providing a TTL logic-low signal. If unused, ground $\overline{\text { RST }}$ or leave it unconnected.

In addition to $\overline{\mathrm{RST}}$, converter 1 also includes a powergood flag. Pull PGOOD1 to a logic voltage to provide logic-level output. PGOOD1 is an open-drain output and can sink 3 mA while providing the TTL logic-low signal. PGOOD1 goes low when converter 1's output drops to $92.5 \%$ of its nominal regulated voltage. Connect PGOOD1 to SGND or leave unconnected, if not used.

## PGOOD1

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

Figure 4. Power-Supply Sequencing Configurations

## Dying Gasp Comparator (PFI/PFO)

The MAX5072 contains an uncommitted comparator with an open-drain output. The inverting input of the comparator is connected to an internal precision 0.78 V reference. Connect the noninverting input (PFI) to VIN through a resistor-divider to program the input trip threshold (VTRIP). The power-fail output (PFO) is pulled low when PFI drops below 0.78 V . PFI provides 20 mV hysteresis to avoid glitches during transition. The PFO signal provides an advance signal to the processor before the converter 1/converter 2 loses regulation. The input trip threshold (VTRIP) can be adjusted to provide advance signaling before the outputs drop to $92.5 \%$ of the regulation voltage.

The input capacitors hold charge and provide energy to the converter after $\mathrm{V}_{\mathrm{IN}}$ is disconnected. The hold-up time (thOLD) is defined as the time when the input voltage drops below VTRIP and the output falls out of regulation at the low end of the input voltage range $\mathrm{VIN}(\mathrm{MIN})$ (Figure 5). Use the following equations to calculate the resistor-divider and the CIN required for the proper hold-up time.

$$
\mathrm{C}_{\text {IN }}=\frac{2\left(\frac{\text { PoUT1 }}{\eta^{1}}+\frac{\text { PoUT2 }^{\eta^{2}}}{\left(\mathrm{~V}_{\text {TRIP }}^{2}-\mathrm{V}^{2} \text { IN(MIN) }\right)}\right.}{x} \times \mathrm{t}_{\text {HOLD }}
$$

where $\eta 1$ and $\eta 2$ are efficiencies of the converter 1 and converter 2, respectively.

Figure 5. Dying Gasp Feature Monitors Input Supply

$$
\mathrm{R} 1=\mathrm{R} 2\left(\frac{\mathrm{~V}_{\text {TRIP }}}{0.78}-1\right)
$$

R2 can be any value from $10 \mathrm{k} \Omega$ to $100 \mathrm{k} \Omega$ (Figure 5).

## Current Limit

The internal switch current of each converter is sensed using an internal current mirror. Converter 1 and converter 2 have 2A and 1A internal switches. When the peak switch current crosses the current-limit threshold of 3A (typ) and 1.8A (typ) for converter 1 and converter 2 , respectively, the on cycle is terminated immediately and the inductor is allowed to discharge. The next cycle resumes at the next clock pulse.

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

In deep overload or short-circuit conditions when the FB voltage drops below 0.4 V , the switching frequency is reduced to $1 / 4 \times$ fsW to provide sufficient time for the inductor to discharge. During overload conditions, if the voltage across the inductor is not high enough to allow for the inductor current to properly discharge, current runaway may occur. Current runaway can destroy the device in spite of internal thermal-overload protection. Reducing the switching frequency during overload conditions prevents current runaway.

## Thermal-Overload Protection

During continuous short circuit or overload at the output, the power dissipation in the IC can exceed its limit. Internal thermal shutdown is provided to avoid irreversible damage to the device. When the die temperature or junction temperature exceeds $+150^{\circ} \mathrm{C}$, an on-chip thermal sensor shuts down the device, forcing the internal switches to turn off, allowing the IC to cool. The thermal sensor turns the part on again after the junction temperature cools by $+30^{\circ} \mathrm{C}$. During thermal shutdown, both regulators shut down, $\overline{\mathrm{RST}}$ goes low, and soft-start resets.

## Applications Information

## Setting the Switching Frequency

The controller generates the clock signal by dividing down the internal oscillator or the SYNC input signal when driven by an external oscillator. The switching frequency equals half the oscillator frequency (fsw = fosc / 2). The internal oscillator frequency is set by a resistor (ROSC) connected from OSC to SGND. The relationship between fsw and ROSC is:

$$
\mathrm{R}_{\mathrm{OSC}}=\frac{12.5 \times 10^{9}}{\mathrm{f}_{\mathrm{SW}}}
$$

where fSW and fosc are in hertz, and ROSC is in ohms. For example, a 1250 kHz switching frequency is set with ROSC $=10 \mathrm{k} \Omega$. Higher frequencies allow designs with lower inductor values and less output capacitance. Consequently, peak currents and $\mathrm{I}^{2} \mathrm{R}$ losses are lower at higher switching frequencies, but core losses, gatecharge currents, and switching losses increase.
A rising clock edge on SYNC is interpreted as a synchronization input. If the SYNC signal is lost, the internal oscillator takes control of the switching rate, returning the switching frequency to that set by ROSC. This maintains output regulation even with intermittent SYNC signals. When an external synchronization signal is used, ROSC should be set for the oscillator frequency to be lower than or equal to the SYNC rate (fsync).

Figure 6. Adjustable Output Voltage

## Buck Converter

Effective Input Voltage Range
Although the MAX5072 converters can operate from input supplies ranging from 4.5 V to 23 V , the input voltage range can be effectively limited by the MAX5072 duty-cycle limitations for a given output voltage. The maximum input voltage is limited by the minimum ontime (tON(MIN)):

$$
\mathrm{V}_{\mathrm{IN}(\mathrm{MAX})} \leq \frac{\mathrm{V}_{\text {OUT }}}{\mathrm{t}_{\mathrm{ON}(\mathrm{MIN})} \times \mathrm{f}_{\mathrm{SW}}}
$$

where $\operatorname{tON}(\mathrm{MIN})$ is 100 ns . The minimum input voltage is limited by the maximum duty cycle ( $\mathrm{DMAX}=0.88$ ):

$$
V_{\text {IN(MIN })}=\left[\frac{V_{\text {OUT }}+V_{\text {DROP1 }}}{0.88}\right]+V_{\text {DROP2 }}-V_{\text {DROP1 }}
$$

where VDROP1 is the total parasitic voltage drops in the inductor discharge path, which includes the forward voltage drop $\left(\mathrm{V}_{\mathrm{D}}\right)$ of the rectifier, the series resistance of the inductor, and the PC board resistance. VDROP2 is the total resistance in the charging path, which includes the on-resistance of the high-side switch, the series resistance of the inductor, and the PC board resistance.

Setting the Output Voltage
For 0.8 V or greater output voltages, connect a voltagedivider from OUT_ to FB_ to SGND (Figure 6). Select RB (FB_ to SGND resistor) to between $1 \mathrm{k} \Omega$ and $10 \mathrm{k} \Omega$. Calculate RA (OUT_ to FB_ resistor) with the following equation:

$$
R_{A}=R_{B}\left[\left(\frac{V_{\mathrm{OUT}}}{V_{\mathrm{FB}}}\right)-1\right]
$$

where $\mathrm{V}_{\mathrm{FB}}=0.8 \mathrm{~V}$ (see the Electrical Characteristics table) and VouT_ can range from VFB_ to 28 V (boost operation).

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

For output voltages below 0.8 V , set the MAX5072 output voltage by connecting a voltage-divider from the output to FB_ to BYPASS (Figure 6). Select Rc (FB to BYPASS resistor) higher than a $50 \mathrm{k} \Omega$ range. Calculate RA with the following equation:

$$
R_{A}=R_{C}\left[\frac{V_{F B}-V_{O U T}}{V_{B Y P A S S}-V_{F B}}\right]
$$

where $\mathrm{V}_{\mathrm{FB}}=0.8 \mathrm{~V}$, $\mathrm{V}_{\mathrm{BYPA}}=2 \mathrm{~V}$ (see the Electrical Characteristics table), and VOUT_ can range from OV to VFB_.

## Inductor Selection

Three key inductor parameters must be specified for operation with the MAX5072: inductance value (L), peak inductor current (IL), and inductor saturation current (ISAT). The minimum required inductance is a function of operating frequency, input-to-output voltage differential and the peak-to-peak inductor current ( $\Delta \mathrm{l} \mathrm{L}$ ). Higher $\Delta \mathrm{IL}$ allows for a lower inductor value while a lower $\Delta \mathrm{I} \mathrm{L}$ requires a higher inductor value. A lower inductor value minimizes size and cost, improves large-signal transient response, but reduces efficiency due to higher peak currents and higher peak-to-peak output ripple voltage for the same output capacitor. On the other hand, higher inductance increases efficiency by reducing the ripple current. However, resistive losses due to extra wire turns can exceed the benefit gained from lower ripple current levels, especially when the inductance is increased without also allowing for larger inductor dimensions. A good compromise is to choose $\Delta \mathrm{I}$ L equal to $30 \%$ of the full load current. To calculate the inductance use the following equation:

$$
L=\frac{V_{O U T}\left(V_{I N}-V_{O U T}\right)}{V_{\text {IN }} \times f_{S W} \times \Delta l_{\mathrm{L}}}
$$

where VIN and VouT are typical values (so that efficiency is optimum for typical conditions). The switching frequency is set by ROSC (see the Setting the Switching Frequency section). The peak-to-peak inductor current, which reflects the peak-to-peak output ripple, is worst at the maximum input voltage. See the Output Capacitor Selection section to verify that the worst-case output ripple is acceptable. The inductor saturating current is also important to avoid runaway current during the output overload and continuous short circuit. Select the ISAT to be higher than the maximum peak current limits of 4.5 A and 2.2A for converter 1 and converter 2.

## Input Capacitors

The discontinuous input current waveform of the buck converter causes large ripple currents at the input. The switching frequency, peak inductor current, and the allowable peak-to-peak voltage ripple dictate the input capacitance requirement. Increasing the switching frequency or the inductor value lowers the peak to average current ratio, yielding a lower input capacitance requirement. Note that two converters of MAX5072 run $180^{\circ}$ out-of-phase, thereby effectively doubling the switching frequency at the input.
The input ripple waveform would be unsymmetrical due to the difference in load current and duty cycle between converter 1 and converter 2 . The input ripple is comprised of $\Delta \mathrm{V}_{\mathrm{Q}}$ (caused by the capacitor discharge) and $\Delta \mathrm{V}_{\mathrm{ESR}}$ (caused by the ESR of the capacitor). A higher load converter dictates the ESR requirement, while the capacitance requirement is a function of the loading mismatch between the two converters. The worst-case mismatch is when one converter is at full load while the other is at no load or in shutdown. Use low-ESR ceramic capacitors with high ripple-current capability at the input. Assume the contribution from the ESR and capacitor discharge equal to $50 \%$. Calculate the input capacitance and ESR required for a specified ripple using the following equations:

$$
\mathrm{ESR}_{\mathrm{IN}}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\left(\mathrm{l} \text { OUT }+\frac{\Delta \mathrm{l}_{\mathrm{L}}}{2}\right)}
$$

where

$$
\Delta L_{\mathrm{L}}=\frac{\left(\mathrm{V}_{\text {IN }}-V_{\text {OUT }}\right) \times V_{\text {OUT }}}{V_{\text {IN }} \times f_{S W} \times L}
$$

and

$$
\mathrm{C}_{\mathrm{IN}}=\frac{\mathrm{IOUT} \times \mathrm{D}(1-\mathrm{D})}{\Delta \mathrm{V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}}
$$

where

$$
\mathrm{D}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{IN}}}
$$

where IOUT is the maximum output current from either converter 1 or converter 2 , and $D$ is the duty cycle for that converter. fSW is the frequency of each individual converter. For example, at V IN $=12 \mathrm{~V}$, VOUT $=3.3 \mathrm{~V}$ at IOUT $=2 \mathrm{~A}$, and with $L=3.3 \mu \mathrm{H}$, the ESR and input capacitance are calculated for a peak-to-peak input

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

ripple of 100 mV or less, yielding an ESR and capacitance value of $20 \mathrm{~m} \Omega$ and $6.8 \mu \mathrm{~F}$ for 1.25 MHz frequency. Use a $100 \mu \mathrm{~F}$ capacitor at low input voltages to avoid possible undershoot below the undervoltage lockout threshold during power-on and transient loading.

## Output Capacitor Selection

The allowable output ripple voltage and the maximum deviation of the output voltage during step load currents determines the output capacitance and its ESR.

The output ripple is comprised of $\Delta \mathrm{V}_{\mathrm{Q}}$ (caused by the capacitor discharge) and $\triangle \mathrm{V}$ ESR (caused by the ESR of the capacitor). Use low-ESR ceramic or aluminum electrolytic capacitors at the output. For aluminum electrolytic capacitors, the entire output ripple is contributed by $\Delta V E S R$. Use the ESROUT equation to calculate the ESR requirement and choose the capacitor accordingly. If using ceramic capacitors, assume the contribution to the output ripple voltage from the ESR and the capacitor discharge are equal. Calculate the output capacitance and ESR required for a specified ripple using the following equations:

$$
\begin{gathered}
\mathrm{ESR}_{\mathrm{OUT}}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\Delta \mathrm{l}_{\mathrm{L}}} \\
\mathrm{C}_{\text {OUT }}=\frac{\Delta \mathrm{l}_{\mathrm{L}}}{8 \times \Delta \mathrm{V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}}
\end{gathered}
$$

where

$$
\Delta \mathrm{V}_{\mathrm{O}} \text { RIPPLE } \cong \Delta \mathrm{V}_{\mathrm{ESR}}+\Delta \mathrm{V}_{\mathrm{Q}}
$$

where $\Delta \mathrm{l} \mathrm{L}$ is the peak-to-peak inductor current as calculated above and fsw is the individual converter's switching frequency.
The allowable deviation of the output voltage during fast transient loads also determines the output capacitance and its ESR. The output capacitor supplies the step load current until the controller responds with a greater duty cycle. The response time (tRESPONSE) depends on the closed-loop bandwidth of the converter. The high switching frequency of MAX5072 allows for higher closed-loop bandwidth, reducing tRESPONSE and the output capacitance requirement. The resistive drop across the output capacitor ESR and the capacitor discharge causes a voltage droop during a step load. Use a combination of low-ESR tantalum and ceramic capacitors for better transient load and ripple/noise performance. Keep the maximum output voltage deviation above the tolerable limits of the elec-
tronics being powered. When using a ceramic capacitor, assume $80 \%$ and $20 \%$ contribution from the output capacitance discharge and the ESR drop, respectively. Use the following equations to calculate the required ESR and capacitance value:

$$
\begin{gathered}
E S R_{\text {OUT }}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\mathrm{I}_{\mathrm{STEP}}} \\
\mathrm{C}_{\mathrm{OUT}}=\frac{\mathrm{I}_{\mathrm{STEP}} \times \mathrm{t}_{\mathrm{RESPONSE}}}{\Delta \mathrm{~V}_{\mathrm{Q}}}
\end{gathered}
$$

where ISTEP is the load step and treSPONSE is the response time of the controller. Controller response time depends on the control-loop bandwidth.

## Boost Converter

The MAX5072 can be configured for step-up conversion since the internal MOSFET can be used as a low-side switch. Use the following equations to calculate the inductor (LMIN), input capacitor (CIN), and output capacitor (COUT) when using the converter in boost operation.

## Inductor

Choose the minimum inductor value so the converter remains in continuous mode operation at minimum output current (IOMIN).

$$
L_{\mathrm{MIN}}=\frac{\mathrm{V}^{2} \mathrm{IN} \times \mathrm{D} \times \eta}{2 \times \mathrm{f}_{\mathrm{SW}} \times \mathrm{V}_{\mathrm{O}} \times \mathrm{I}_{\mathrm{OMIN}}}
$$

where

$$
D=\frac{V_{O}+V_{D}-V_{I N}}{V_{O}+V_{D}-V_{D S}}
$$

and $\mathrm{IOMIN}=0.25 \times \mathrm{IO}$
The $V_{D}$ is the forward voltage drop of the external Schottky diode, $D$ is the duty cycle, and $V_{D S}$ is the voltage drop across the internal switch. Select the inductor with low DC resistance and with a saturation current (ISAT) rating higher than the peak switch current limit of 4.5 A and 2.2A of converter 1 and converter 2, respectively.

## Input Capacitor

The input current for the boost converter is continuous and the RMS ripple current at the input is low. Calculate the capacitor value and ESR of the input capacitor using the following equations.

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

$$
\begin{gathered}
\mathrm{C}_{\mathrm{IN}}=\frac{\Delta \mathrm{I}_{\mathrm{L}} \times \mathrm{D}}{4 \times \mathrm{f}_{\mathrm{SW}} \times \Delta \mathrm{V}_{\mathrm{Q}}} \\
\mathrm{ESR}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\Delta \mathrm{I}_{\mathrm{L}}}
\end{gathered}
$$

where

$$
\Delta L_{L}=\frac{\left(V_{I N}-V_{D S}\right) \times D}{L \times f_{S W}}
$$

where VDS is the total voltage drop across the internal MOSFET plus the voltage drop across the inductor ESR. $\Delta I \mathrm{~L}$ is the peak-to-peak inductor ripple current as calculated above. $\Delta \mathrm{V}_{\mathrm{Q}}$ is the portion of input ripple due to the capacitor discharge and $\Delta \mathrm{V}_{\mathrm{ESR}}$ is the contribution due to ESR of the capacitor.

## Output Capacitor Selection

For the boost converter, the output capacitor supplies the load current when the main switch is ON. The required output capacitance is high, especially at higher duty cycles. Also, the output capacitor ESR needs to be low enough to minimize the voltage drop due to the ESR while supporting the load current. Use the following equation to calculate the output capacitor for a specified output ripple tolerance.

$$
\begin{gathered}
\mathrm{ESR}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\mathrm{I}_{\mathrm{O}}} \\
\mathrm{C}_{\mathrm{OUT}}=\frac{\mathrm{I}_{\mathrm{O}} \times \mathrm{D}_{\mathrm{MAX}}}{\Delta \mathrm{~V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}}
\end{gathered}
$$

IO is the load current, $\Delta \mathrm{V}_{\mathrm{Q}}$ is the portion of the ripple due to the capacitor discharge and $\Delta \mathrm{V}$ ESR is the contribution due to the ESR of the capacitor. Dmax is the maximum duty cycle at minimum input voltage.

## Power Dissipation

The MAX5072 includes a high-frequency, low RDS_ON switching MOSFET. At $+85^{\circ} \mathrm{C}$, the RDS_ON of the internal switch for converter 1 and converter 2 are $290 \mathrm{~m} \Omega$ and $630 \mathrm{~m} \Omega$, respectively. The DC loss is a function of the RMS current in the switch while the switching loss is a function of switching frequency and input voltage. Use the following equations to calculate the RMS current, DC loss, and switching loss of each converter. The MAX5072 device is available in a thermally enhanced package and can dissipate up to 2.7 W at $+70^{\circ} \mathrm{C}$ ambi-

Figure 7. Type II Compensation Network.

Figure 8. Type III Compensation Network
ent temperature. The total power dissipation in the package must be limited so the junction temperature does not exceed its absolute maximum rating of $+150^{\circ} \mathrm{C}$ at maximum ambient temperature.
For the buck converter:

$$
\begin{aligned}
& I_{\mathrm{RMS}}= \sqrt{\left(I^{2} \mathrm{DC}+1^{2}{ }_{\mathrm{PK}}+\left(I_{\mathrm{DC}} \times I_{\mathrm{PK}}\right)\right) \times \frac{\mathrm{D}_{\mathrm{MAX}}}{3}} \\
& \mathrm{P}_{\mathrm{DC}}=1^{2}{ }_{\mathrm{RMS}} \times \mathrm{R}_{\mathrm{DS}(\mathrm{ON}) \mathrm{MAX}}
\end{aligned}
$$

where

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{DC}}=\mathrm{I}_{\mathrm{O}}-\frac{\Delta \mathrm{I}_{\mathrm{L}}}{2} \\
& \mathrm{I}_{\mathrm{PK}}=\mathrm{I}_{\mathrm{O}}+\frac{\Delta \mathrm{I}_{\mathrm{L}}}{2}
\end{aligned}
$$

See the Electrical Characteristics table for the RDS(ON)MAX value.

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

$$
P_{S W}=\frac{V_{\text {INMAX }} \times I_{O} \times\left(t_{R}+t_{F}\right) \times f_{S W}}{4}
$$

For the boost converter:

$$
\begin{aligned}
& I_{R M S}=\sqrt{\left(1^{2} D C+1^{2}{ }_{P K}+\left(I_{D C} \times I_{P K}\right)\right) \times \frac{D_{M A X}}{3}} \\
& I_{N}=\frac{V_{O} \times I_{O}}{V_{I N} \times \eta} \\
& \Delta_{L}=\frac{\left(V_{I N}-V_{D S}\right) \times D}{L \times f_{S W}} \\
& l_{D C}=I_{N}-\frac{\Delta L_{L}}{2} \\
& I_{P K}=I_{I N}+\frac{\Delta L_{\mathrm{L}}}{2} \\
& P_{D C}=I^{2}{ }_{\text {RMS }} \times R_{\text {DS(ON }) M A X}
\end{aligned}
$$

where VDS is the drop across the internal MOSFET. See the Electrical Characteristics for the RDS(ON)MAX value.

$$
P_{S W}=\frac{V_{O} \times l_{I N} \times\left(t_{R}+t_{F}\right) \times f_{S W}}{4}
$$

where $t_{R}$ and $t_{F}$ are rise and fall times of the internal MOSFET. The tR and tF are typically 20ns, and can be measured in the actual application.
The supply current in the MAX5072 is dependent on the switching frequency. See the Typical Operating Characteristics to find the supply current of the MAX5072 at a given operating frequency. The power dissipation (Ps) in the device due to supply current (IS) is calculated using following equation.

$$
P_{S}=V_{I N M A X} \times I_{\text {SUPPLY }}
$$

The total power dissipation PT in the device is:

$$
P T=P D C 1+P D C 2+P S W 1+P S W 2+P S
$$

where PDC1 and PDC2 are DC losses in converter 1 and converter 2, respectively. PSW1 and PSW2 are switching losses in converter 1 and converter 2, respectively.
Calculate the temperature rise of the die using the following equation:

$$
\mathrm{T}_{\mathrm{J}}=\mathrm{T}_{\mathrm{C}}+\left(\mathrm{PT} \times \theta_{\mathrm{J}}-\mathrm{C}\right)
$$

where $\theta \mathrm{J}$ - C is the junction-to-case thermal impedance of the package equal to $+2^{\circ} \mathrm{C} / \mathrm{W}$. Solder the exposed pad of the package to a large copper area to minimize the case-to-ambient thermal impedance. Measure the temperature of the copper area near the device at a worst-case condition of power dissipation and use $+2^{\circ} \mathrm{C} / \mathrm{W}$ as $\theta_{\mathrm{J}}$ - thermal impedance. The case-to-ambient thermal impedance ( $\theta \mathrm{C}-\mathrm{A}$ ) is dependent on how well the heat is transferred from the PC board to the ambient. Use large copper area to keep the PC board temperature low. The $\theta \mathrm{C}-\mathrm{A}$ is usually in the $+20^{\circ} \mathrm{C} / \mathrm{W}$ to $+40^{\circ} \mathrm{C} / \mathrm{W}$ range.

## Compensation

The MAX5072 provides an internal transconductance amplifier with its inverting input and its output available to the user for external frequency compensation. The flexibility of external compensation for each converter offers wide selection of output filtering components, especially the output capacitor. For cost-sensitive applications, use high-ESR aluminum electrolytic capacitors; for component size-sensitive applications, use low-ESR tantalum or ceramic capacitors at the output. The high switching frequency of MAX5072 allows use of ceramic capacitors at the output.
Choose all the passive power components that meet the output ripple, component size, and component cost requirements. Choose the small-signal components for the error amplifier to achieve the desired closed-loop bandwidth and phase margin. Use a simple pole-zero pair (Type II) compensation if the output capacitor ESR zero frequency is below the unity-gain crossover frequency (fc). Type III compensation is necessary when the ESR zero frequency is higher than fc or when compensating for a continuous mode boost converter that has a right-half plane zero.
Use the following procedure 1 to calculate the compensation network components when $\mathrm{fZERO}, \mathrm{ESR}<\mathrm{fC}$.

Buck Converter Compensation
Procedure 1 (see Figure 7):
Calculate the fZERO,ESR and LC double pole:

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

$$
\begin{aligned}
& \mathrm{f}_{\text {ZERO }}, \mathrm{ESR}=\frac{1}{2 \pi \times \mathrm{ESR} \times \mathrm{C}_{\text {OUT }}} \\
& \mathrm{f}_{\mathrm{LC}}=\frac{1}{2 \pi \times \sqrt{\text { LOUT } \times \mathrm{C}_{\text {OUT }}}}
\end{aligned}
$$

Calculate the unity-gain crossover frequency as:

$$
\mathrm{f}_{\mathrm{C}}=\frac{\mathrm{f}_{\mathrm{SW}}}{20}
$$

If the fZERO,ESR is lower than fC and close to flC, use a Type II compensation network where RFCF provides a midband zero fmid,zero, and RFCCF provides a high-frequency pole.
Calculate modulator gain $\mathrm{Gm}_{\mathrm{M}}$ at the crossover frequency.

$$
G_{M}=\frac{V_{I N}}{V_{O S C}} \times \frac{E S R}{E S R+2 \pi \times f_{C} \times L_{O U T}} \times \frac{0.8}{V_{\text {OUT }}}
$$

where VOSC is a peak-to-peak ramp amplitude equal to 1 V .

Figure 9. Buck-Boost Application

### 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output

The transconductance error-amplifier gain is:

$$
G_{E / A}=g_{m} \times R_{F}
$$

The total loop gain at fc should be equal to 1

$$
G_{M} \times G_{E / A}=1
$$

or

$$
R_{F}=\frac{V_{\text {OSC }}\left(E S R+2 \pi \times f_{C} \times L_{\text {OUT }}\right) V_{\text {OUT }}}{0.8 \times V_{I N} \times g_{m} \times E S R}
$$

Place a zero at or below the LC double pole:

$$
C_{F}=\frac{1}{2 \pi \times R_{F} \times f_{L C}}
$$

Place a high-frequency pole at $f p=0.5 \times f s w$.

## Procedure 2 (See Figure 8):

If the output capacitor used is a low-ESR ceramic type, the ESR frequency is usually far away from the targeted unity crossover frequency (fC). In this case, Type III compensation is recommended. Type III compensation provides two-pole zero pairs. The locations of the zero and poles should be such that the phase margin peaks at $\mathrm{f} c$.
The $\frac{\mathrm{f}_{\mathrm{C}}}{\mathrm{f}_{\mathrm{Z}}}=\frac{\mathrm{f}_{\mathrm{p}}}{\mathrm{f}_{\mathrm{C}}}=5$
is a good number to get about $60^{\circ}$ phase margin at fc . However, it is important to place the two zeros at or below the double pole to avoid the conditional stability issue.
Select a crossover frequency:

$$
f_{C} \leq \frac{f_{S W}}{20}
$$

Calculate the LC double-pole frequency, fLC:

$$
f_{\text {LC }}=\frac{1}{2 \pi \times \sqrt{\text { LOUT } \times \mathrm{C}_{\text {OUT }}}}
$$

Place a zero

$$
f_{Z}=\frac{1}{2 \pi \times R_{F} \times C_{F}} \text { at } 0.75 \times f_{L C}
$$

where:

$$
C_{F}=\frac{1}{2 \pi \times 0.75 \times f_{L C} \times R_{F}}
$$

and $R F \geq 10 k \Omega$.

Calculate Cl for a target unity crossover frequency, fC:

$$
C_{I}=\frac{2 \pi \times f_{\mathrm{C}} \times \mathrm{L}_{\mathrm{OUT}} \times \mathrm{C}_{\text {OUT }} \times \mathrm{V}_{\text {OSC }}}{V_{\text {IN }} \times R_{\mathrm{F}}}
$$

Place a pole ${ }^{\left(f_{P 1}=\frac{1}{2 \pi \times R_{I} \times C_{I}} \text { at fZERO,ESR. }\right.}$

$$
\mathrm{R}_{\mathrm{l}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{ZERO}, \mathrm{ESR}} \times \mathrm{C}_{l}}
$$

Place a second zero, fz2, at 0.2fc or at fLC, whichever is lower.

$$
R 1=\frac{1}{2 \pi \times f_{Z 2} \times C_{l}}-R_{l}
$$

Place a second pole $\left(f_{\text {P2 }}=\frac{1}{2 \pi \times R_{F} \times C_{C F}}\right)$ at $1 / 2$ the switching frequency.

$$
C_{C F}=\frac{C_{F}}{\left(2 \pi \times 0.5 \times f_{S W} \times R_{F} \times C_{F}\right)-1}
$$

## Boost Converter Compensation

The boost converter compensation gets complicated due to the presence of a right-half-plane zero FZERO,RHP. The right-half-plane zero causes a drop inphase while adding positive (+1) slope to the gain curve. It is important to drop the gain significantly below unity before the RHP frequency. Use the following procedure to calculate the compensation components.
Calculate the LC double-pole frequency, fLC, and the right half plane zero frequency.

$$
\begin{aligned}
& f_{\text {LC }}=\frac{1-\mathrm{D}}{2 \pi \times \sqrt{\text { LOUT }_{\text {OUT }}}} \\
& f_{\text {ZERO, }} \text { RHP }=\frac{(1-D)^{2} R_{(\text {MIN })}}{2 \pi \times L_{\text {OUT }}}
\end{aligned}
$$

where:

$$
\begin{aligned}
& D=1-\frac{V_{I N}}{V_{\text {OUT }}} \\
& R_{(M I N)}=\frac{V_{\text {OUT }}}{I_{\text {OUT(MAX) }}}
\end{aligned}
$$

Target the unity-gain crossover frequency for:

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

$$
\begin{aligned}
f_{C} & \leq \frac{f_{Z E R O}, R H P}{5} \\
\left(f_{Z 1}\right. & \left.=\frac{1}{2 \pi \times R_{F} \times C_{F}}\right) \text { at } 0.75 \times f L C . \\
C_{F} & =\frac{1}{2 \pi \times 0.75 \times f_{L C} \times R_{F}}
\end{aligned}
$$

where $R_{F} \geq 10 \mathrm{k} \Omega$.
Calculate $\mathrm{Cl}_{\mathrm{I}}$ for a target crossover frequency, fC:

$$
C_{I}=\frac{V_{\text {OSC }}\left[(1-D)^{2}+\omega_{C}^{2} \times L_{O} \times C_{O}\right]}{\omega_{C} \times R_{F} \times V_{I N}}
$$

where $\omega \mathrm{c}=2 \pi \mathrm{f} \mathrm{C}$.

Place a pole

$$
\left(\mathrm{f}_{\mathrm{P} 1}=\frac{1}{2 \pi \times \mathrm{R}_{\mid} \times \mathrm{C}_{\mid}}\right. \text {at fZERO,RHP. }
$$

$$
R_{l}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{ZERO}}, R H P \times \mathrm{C}_{l}}
$$

Place the second zero $\quad\left(\mathrm{f}_{\mathrm{Z} 2}=\frac{1}{2 \pi \times R_{1} \times \mathrm{C}_{l}}\right)$ at fLC .

$$
R_{1}=\frac{1}{2 \pi \times f_{L C} \times C_{\mid}}-R_{\mid}
$$

Place the second pole

$$
\left(f_{P 2}=\frac{1}{2 \pi \times R_{F} \times C_{C F}}\right)
$$ the switching frequency.

$$
C_{C F}=\frac{C_{F}}{\left(2 \pi \times 0.5 f_{S W} \times R_{F} \times C_{F}\right)-1}
$$

Improving Noise Immunity
In applications where the MAX5072 are subject to noisy environments, adjust the controller's compensation to improve the system's noise immunity. In particular, high-frequency noise coupled into the feedback loop causes jittery duty cycles. One solution is to lower the crossover frequency (see the Compensation section).

PC Board Layout Guidelines
Careful PC board layout is critical to achieve low switching losses and clean, stable operation. This is especially true for dual converters where one channel can affect the other. Refer to the MAX5072 EV kit data sheet for a specific layout example. Use a multilayer board whenever possible for better noise immunity. Follow these guidelines for good PC board layout:

1) For SGND, use a large copper plane under the IC and solder it to the exposed paddle. To effectively use this copper area as a heat exchanger between the PC board and ambient, expose this copper area on the top and bottom side of the PC board. Do not make a direct connection from the exposed pad copper plane to SGND (pin 29) underneath the IC.
2) Isolate the power components and high-current path from the sensitive analog circuitry. Use a separate PGND plane under the OUT1 and OUT2 sides (referred to as PGND1 and PGND2). Connect the PGND1 and PGND2 planes together at one point near the IC.
3) Keep the high-current paths short, especially at the ground terminals. This practice is essential for stable, jitter-free operation.
4) Connect SGND and PGND together close to the IC at the ground terminals of $V L$ and $V+$ bypass capacitors. Do not connect them together anywhere else.
5) Keep the power traces and load connections short. This practice is essential for high efficiency. Use thick copper PC boards (2oz vs. 1oz) to enhance full-load efficiency.
6) Ensure that the feedback connection to Cout is short and direct.
7) Route high-speed switching nodes (BST_/VDD_, SOURCE_) away from the sensitive analog areas (BYPASS, COMP_, and FB_). Use the internal PC board layer for SGND as EMI shields to keep radiated noise away from the IC, feedback dividers, and analog bypass capacitors.

# 2.2MHz, Dual-Output Buck or Boost Converter with POR and Power-Fail Output 

## Layout Procedure

1) Place the power components first, with ground terminals adjacent (inductor, CIN_, and COUT_). Make all these connections on the top layer with wide, copper-filled areas (2oz copper recommended).
2) Group the gate-drive components (bootstrap diodes and capacitors, and VL bypass capacitor) together near the controller IC.
3) Make the DC-DC controller ground connections as follows:
a) Create a small-signal ground plane underneath the IC.

Ordering Information (continued)

| PART | TEMP RANGE | PIN-PACKAGE | PKG <br> CODE |
| :---: | :---: | :--- | :---: |

Package Information (continued)
(The package drawing(s) in this data sheet may not reflect the most current specifications. For the latest package outline information go to www.maxim-ic.com/packages.)

NOTES:

1. DIMENSIONING \& TOLERANCING CONFORM TO ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS. ANGLES ARE IN DEGREES.
3. N IS THE TOTAL NUMBER OF TERMINALS.
4. THE TERMINAL \#1 IDENTIFIER AND TERMINAL NUMBERING CONVENTION SHALL CONFORM TO JESD 95-1 SPP-012. DETAILS OF TERMINAL \#1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE TERMINAL \#1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE.
5. DIMENSION b APPLIES TO METALLIZED TERMINAL AND IS MEASURED BETWEEN 0.25 mm AND 0.30 mm FROM TERMINAL TIP
6. ND AND NE REFER TO THE NUMBER OF TERMINALS ON EACH D AND E SIDE RESPECTIVELY.
7. DEPOPULATION IS POSSIBLE IN A SYMMETRICAL FASHION
8. COPLANARITY APPLIES TO THE EXPOSED HEAT SINK SLUG AS WELL AS THE TERMINALS.
9. DRAWING CONFORMS TO JEDEC MO220, EXCEPT EXPOSED PAD DIMENSION FOR T2855-3 AND T2855-6.
4 WARPAGE SHALL NOT EXCEED 0.10 mm .
10. MARKING IS FOR PACKAGE ORIENTATION REFERENCE ONLY
11. NUMBER OF LEADS SHOWN ARE FOR REFERENCE ONLY.
12. LEAD CENTERLINES TO BE AT TRUE POSITION AS DEFINED BY BASIC DIMENSION "e", $\pm 0.05$.
