

ZXCD50STEVAL

50W CLASS D AUDIO AMPLIFIER EVALUATION BOARD

DESCRIPTION

The ZXCD50STEVAL evaluation board is based on the ZXCD1000 Class D audio amplifier solution from Zetex. This board allows the user to evaluate the high fidelity audio performance offered by the Zetex solution, with an output power up to 50W music power into 4Ω.

INTRODUCTION

The ZXCD50STEVAL is a 50W music power (4Ω load) high performance class D amplifier. The circuitry contains MOSFET devices and should therefore be handled appropriately.

The board requires a single rail power supply of 13 volts minimum and 25 volts maximum. Voltages in excess of 25 volts may cause permanent damage to the board.

The heart of the solution is the ZXCD1000 class D controller IC and the user should refer to the ZXCD1000 data sheet for further technical information. The circuit features pop suppression and over current protection as well as a mute facility.

FEATURES

- Stereo
- Class D architecture
- Single power supply
- Output power ($V_{supply} = 25V$)
 - 50W music into 4Ω
 - 25W music into 8Ω
- THD + N <0.5% @ 90% power
- >90% efficiency
- Flat frequency response 20Hz – 20 kHz
- Turn on / turn off pop suppression
- Over current protection
- Mute facility
- Noise floor -115dB

Note: The ZXCD50STEVAL is intended as an evaluation platform for Zetex Class D solutions. Zetex accepts no liability for external equipment connected to the ZXCD50STEVAL or any other form of consequential damage or loss.

ZXCD50STEVAL

CONNECTION AND OPERATION

The following PCB image shows the connections required for correct operation of the ZXCD50STEVAL board. Simple connector blocks are provided to enable easy connection of the supply voltage, audio inputs and speaker outputs.

Power connection

The ZXCD50STEVAL requires a single positive supply voltage:

25V @ approximately 2.3A for 50W music into 4Ω

Note: 8Ω speakers can be used in this application. In this case a 25V bridge supply will result in an output power of 25W music. If this is required then C2/102 should be removed to maintain a flat frequency response.

The supply should not exceed 25V and must not be less than 13V to ensure correct operation of the amplifier. Ensure the correct polarity of the supply applied.

Audio input

The ZXCD50STEVAL requires a single ended audio input per channel as follows:

The input impedance is 18kΩ.

Input signal amplitude required for full output power is approximately 2.5V peak to peak.

Speaker connection

4Ω speakers may be connected to the board as shown. The correct polarity connection of the speakers is essential to avoid phasing errors.

Note: 8Ω speakers can be used in this application. If this is required then C2/102 should be removed to maintain a flat frequency response.

Over current protection is provided on the board, which prevents damage to the circuit with shorts from the speaker to ground or across the speaker.

EVALUATION BOARD DESCRIPTION AND OPERATION

The top copper, bottom copper and silk screen ID overlay are shown in figure 1,2 and 3.

The ZXCD1000 is available in a 16-pin exposed pad QSOP package. The exposed pad on the underside of the package is soldered down to an area of copper on the PCB, to function as a heatsink. To further assist heat dissipation, the PCB has plated through vias connecting to an area of copper on the underside of the board.

The MOSFETS required on the board are Zetex ZXM64 series HDMOS parts. These SOT223 parts are required to handle the power dissipation in the amplifier with a 50W music load.

The regulator transistors on the board are ZTX692B, E-Line devices. These devices are required to supply the 12V rail to the channels from the board input voltage which is the 25V bridge supply.

The inductors in place on the board have been selected for their excellent linearity and low losses. These components ensure minimal distortion is introduced in the recovered audio signal across the full power band.

The speaker is connected as a Bridge Tied Load (BTL). This means that both sides of the speaker are driven from the Output Bridge and therefore neither side of the speaker connects to ground. This allows maximum power to be delivered to the load, from a given supply voltage.

ZXCD50STEVAL

If it is wished to view or measure the signal across the load, a floating monitor must be used - for example a differential probe. Alternatively this may be achieved with a two channel oscilloscope monitoring the speaker A and speaker B outputs, and using the invert and add functions. For diagnostic purposes, the speaker outputs can be monitored single-ended with respect to ground with an oscilloscope (or other instrument) if desired. However any results obtained in this manner, are not valid for assessing performance. The true performance depends upon some differential cancellation across the speaker load.

The board requires an input signal of 2.5V peak to peak nominal to yield the full output power. The input impedance of the board is nominally 18k Ω . This may attenuate the source voltage and may need to be allowed for, depending on the output impedance of the source.

The maximum supply voltage to the ZXCD50STEVAL evaluation board is 25V nominal. A supply voltage of 25V will achieve 50W music into a 4 Ω load.

ZXCD50STEVAL

ZXCD50STEVAL CIRCUIT DESCRIPTION.

Proprietary circuit design and high quality magnetics are necessary to yield the excellent THD performance of the solution. At the heart of the circuit is the Zetex ZXCD1000 class D audio IC.

The ZXCD50STEVAL circuit diagram is shown in figure 4. The board features two class D channels, one master and one slave. These channels are essentially the same other than the triangle synchronisation facilitated by Q1 on the master channel.

Each audio channel consists of an input phase splitter, the ZXCD1000, an output bridge to drive the load - via L-C filters, and an over-current protection circuit. Each channel also features its own dropper voltage regulator.

The voltage regulator (Q5/105, ZD1/101 etc.) is necessary to drop higher supply voltages (25V on the bridge for 50W) to a level suitable for the ZXCD1000 and input phase splitter (12V on the board).

The input phase splitter per channel, built around the NE5532 dual op amp, is necessary to drive the Audio A and Audio B channels on each ZXCD1000.

Each channel phase splitter features a mute transistor (Q11/111) which is controlled via the circuit built around Q12. This circuit provides a mute function with an active low input. The mute function reduces the effective output signal by 54dB.

The Output Bridges are built around the Zetex XXM64P035G and XXM64N035G PMOS and NMOS SOT223 transistors.

The circuit built around Q10 facilitates a slow start for the bridge supply voltage. This circuit performs anti-pop for the solution.

R20/120 are over current sense resistors. The circuit built around these (Q2/102, Q3/103 etc) enables an over-current protection for the solution. In fault conditions the circuit disables the triangle modulation waveform to the channel and thus disables the output bridge. Protection is given for speaker shorts and speaker to ground shorts.

The ZXCD1000 outputs drive Output Bridge MOSFET's, with the PWM signal, which subsequently drives the load via L-C filters. The purpose of the filters is to low pass filter the high frequency switching PWM signal from the bridge. Thus the lower frequency audio signal is recovered and is available at the speaker outputs.

ZXCD50STEVAL CIRCUIT PERFORMANCE

The graph shown in fig 5 indicates the typical THD performance of the solution. THD is shown from zero up to full power.

Distortion is sub 1% all the way up to full power, typically at 1W 1kHz distortion is 0.1%.

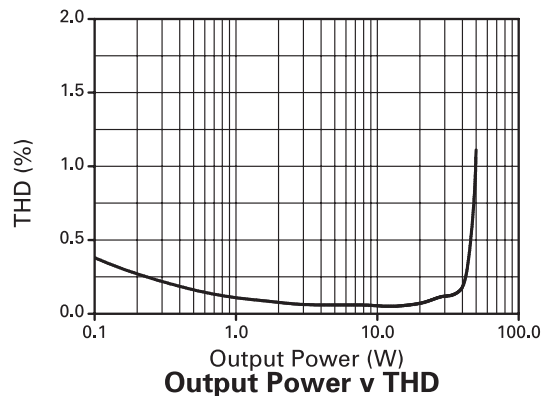

Figure 5.

WARNING - Appropriate safety precautions should be taken by a competent person if the ZXCD1000MOEVAL is to be connected to any potentially hazardous equipment.

ZXCD50STEVAL

Notes.
