

## Parallax GPS Receiver Module

### Introduction

Designed in cooperation with Grand Idea Studio (<http://www.grandideastudio.com/>), the Parallax Global Positioning System (GPS) Receiver Module is a fully integrated, low-cost unit complete with on-board patch antenna. Based around the Polstar (<http://www.polstargps.com/>) PMB-248, the GPS Receiver Module is a complete GPS solution in a very small footprint (1.92" long x 1.42" wide).

The GPS Receiver Module provides standard, raw NMEA0183 (National Marine Electronics Association) strings or specific user-requested data via the serial command interface, tracking of up to 12 satellites, and WAAS/EGNOS (Wide Area Augmentation System/European Geostationary Navigation Overlay Service) functionality for more accurate positioning results.

The Module provides current time, date, latitude, longitude, altitude, speed, and travel direction/heading, among other data, and can be used in a wide variety of hobbyist and commercial applications, including navigation, tracking systems, mapping, fleet management, auto-pilot, and robotics.

### Module Highlights

- Fully-integrated, low-cost GPS receiver module with on-board, passive patch antenna
- Single-wire, 4800 baud Serial TTL interface to BASIC Stamp®, SX, Propeller, and other processors
- Provides either raw NMEA0183 strings or specific data requested via the command interface
- Requires single +5VDC supply @ 115mA (typical)
- 0.100" pin spacing for easy prototyping and integration

- Programmable Parallax SX/B microprocessor and open-source control firmware for advanced users (not supported by Parallax, but offered as a download from the Parallax web site)

## Electronic Connections

Pin	Pin Name	Type	Function
1	GND	G	System ground. Connect to power supply's ground (GND) terminal.
2	VCC	P	System power, +5V DC input.
3	SIO	I/O	Serial communication (commands sent TO the Module and data received FROM the Module). Asynchronous, TTL-level interface, 4800bps, 8 data bits, no parity, 1 stop bit, non-inverted.
4	/RAW	I	Mode select pin. Active LOW digital input. Internally pulled HIGH by default. When the /RAW pin is unconnected, the default "Smart Mode" is enabled, wherein commands for specific GPS data can be requested and the results will be returned (see the "Command Structure" section for more details). When /RAW is pulled LOW, the Module will enter "Raw Mode" and will transmit standard strings, allowing advanced users to use the raw GPS data directly.

Note: Type: I = Input, O = Output, P = Power, G = Ground

The GPS Receiver Module can be integrated into any design using a minimum of three connections. Use the following circuit for connecting the GPS Receiver Module to the BASIC Stamp microcontroller:

The on-board, four-pin header allows the GPS Receiver Module to be plugged into a solderless breadboard (on a Boe-Bot, for example). If the default "Smart Mode" is desired and the /RAW pin will be unused, the Module can be simply connected to its host with a standard three-pin servo extension cable.

The Module is designed to mount horizontally, so the antenna can face to the sky. Screw holes are located on each corner for more solid mounting if the user desires.

**The Module must be used outdoors or with a clear view of the sky in order for it to fix on satellites - this is the nature of GPS and not a limitation of our product.** With an unobstructed, clear view of the sky, GPS works anywhere in the world, 24 hours a day, seven days a week. Please note that some products, such as motors, computers, and wireless/RF devices, which emit high levels of magnetic field and interference, may prevent the Module from receiving the required GPS signals from the satellites and may cause the performance of the Module to decrease. Additionally, when using the Module in automobile applications, the optimal position for the Module is mounted on the rooftop of the vehicle. If the Module is to be used inside the car, ensure that the Module's antenna still has a clear view of the sky, such as by placing it on the dashboard, and is not blocked by any metal objects within the car.

For more information on GPS functionality, see the “GPS Technology Brief” section.

## Status Indicators

The GPS Receiver Module contains a single red LED (light-emitting diode) to denote system status. The LED is located in the lower-right corner of the Module. A white overlay on the Module’s printed circuit board is used to reflect the light from the LED, making it easier for the user to see. The LED denotes two states of the Module:

- 1) **Blinking** (both fast and slow): Searching for satellites or no satellite fix acquired
- 2) **Solid**: Satellites successfully acquired (a minimum of three satellites is required before the Module will begin to transmit valid GPS data)

**Upon power up of the GPS Receiver Module in a new location, the Module may take up to five minutes or more to acquire a fix on the necessary minimum number of four satellites.** During this time, the red LED on the Module will blink. When enough satellites are acquired for the Module to function properly, the red LED will remain solid red. Due to a variety of conditions, the number of satellites may vary at any given time.

If the LED is OFF, there may be a problem. Please check your wiring and configuration of the Module.

## Mode Selection

The /RAW pin allows user selection of the GPS Receiver Module’s two operating modes:

- **Smart Mode:** When the /RAW pin is pulled HIGH or simply left unconnected (the pin is internally pulled HIGH), the default “Smart Mode” is enabled, wherein commands for specific GPS data can be requested and the results will be returned. See the “Communication Protocol” section for more details.
- **Raw Mode:** When the /RAW pin is pulled LOW, “Raw Mode” is enabled in which the Module will transmit standard NMEA0183 v2.2 strings (GGA, GSV, GSA, and RMC), allowing advanced users to use the raw GPS data directly. For more information on NMEA0183 data, see the “GPS Technology Brief” section.

In either mode, data is transmitted at 4800bps, 8 data bits, no parity, 1 stop bit, non-inverted, TTL-level.

## Communication Protocol (for use in “Smart Mode” only)

Implementation and usage of the GPS Receiver Module is straightforward. A BASIC Stamp 2 code example is included at the end of this documentation.

The GPS Receiver Module is controlled by the host via an easy-to-use, TTL-level, asynchronous serial communications interface. The command structure and communication is compatible with Parallax’s AppMod serial protocol. The single SIO pin transfers commands sent TO the Module and data received FROM the Module. All communication is at 4800bps, 8 data bits, no parity, 1 stop bit, non-inverted.

To send a command to the GPS Receiver Module, the user must first send the header string, which is “!GPS” without the quotes, followed by the specific command byte of their choice.

Each command consists of a single byte in hexadecimal. Depending on the command, a specific number of data bytes will be returned. The complete command list and returned variables are as follows:

Cmd	Constant	Description	Returned Bytes	Variables (1 Byte Each Unless Noted)
0x00	GetInfo	GPS Receiver Module version	2	Hardware, Firmware
0x01	GetValid	Check validity of data string	1	0 = Not Valid, 1 = Valid
0x02	GetSats	Number of acquired satellites (12 maximum)	1	
0x03	GetTime	Time (UTC/Greenwich Mean Time)	3	Hours, Minutes, Seconds
0x04	GetDate	Date (UTC/Greenwich Mean Time)	3	Month, Day, Year
0x05	GetLat	Latitude	5	Degrees, Minutes, Fractional Minutes (Word), Direction (0 = N, 1 = S)
0x06	GetLong	Longitude	5	Degrees, Minutes, Fractional Minutes (Word), Direction (0 = E, 1 = W)
0x07	GetAlt	Altitude above mean-sea-level (in tenths of meters, 65535 maximum)	2	Altitude (Word)
0x08	GetSpeed	Speed (in tenths of knots)	2	Speed (Word)
0x09	GetHead	Heading/direction of travel (in tenths of degrees)	2	Heading (Word)

### Other Specifications

- The navigation update rate of the GPS Receiver Module is once per second.
- High sensitivity (-152 dBm for tracking and -139 dBm for acquisition).
- The Module contains a built-in rechargeable battery for memory and real-time clock back-up.
- On average, the Module has a +/-5 meter position accuracy and a +/-0.1 meter per second velocity accuracy.

### Electrical Characteristics

#### Absolute Maximum Ratings

Condition	Value
Operating Temperature	-40°C to +85°C
Storage Temperature	-55°C to +100°C
Supply Voltage (V <sub>CC</sub> )	+4.5V to +5.5V
Ground Voltage (V <sub>SS</sub> )	0V
Voltage on any pin with respect to V <sub>SS</sub>	-0.6V to +(V <sub>CC</sub> +0.6)V

**NOTICE:** Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

## DC Characteristics

At  $V_{CC} = +5.0V$  and  $T_A = 25^{\circ}C$  unless otherwise noted

Parameter	Symbol	Test Conditions	Specification			Unit
			Min.	Typ./Avg.	Max.	
Supply Voltage	$V_{CC}$	---	4.5	5.0	5.5	V
Supply Current, Active	$I_{CC}$	---	80	115	135	mA

## GPS Technology Brief

*Some material in this section is based on information provided by the Global Position System FAQ (<http://www.gpsy.com/gpsinfo/gps-faq.txt>)*

Developed and operated by the United States government, GPS (Global Positioning System) is a worldwide radio-navigation system formed by a constellation of 24 satellites and their ground stations. With an unobstructed, clear view of the sky, GPS works anywhere in the world, 24 hours a day, seven days a week.

The Global Positioning System consists of three interacting components:

- 1) **The Space Segment** -- satellites orbiting the earth.
- 2) **The Control Segment** -- the control and monitoring stations run by the United States Department of Defense (not discussed in this documentation).
- 3) **The User Segment** -- the GPS signal receivers owned by civilians and military.

The space segment consists of a constellation of 24 active satellites (and one or more in-orbit spares) orbiting the earth every 12 hours. Four satellites are located in each of six orbits and will be visible from any location on each 95 percent of the time. The orbits are distributed evenly around the earth, and are inclined 55 degrees from the equator. The satellites orbit at an altitude of about 11,000 nautical miles.

Each satellite transmits two signals: L1 (1575.42 MHz) and L2 (1227.60 MHz). The L1 signal is modulated with two pseudo-random noise signals - the protected (P) code, and the course/acquisition (C/A) code. The L2 signal only carries the P code. Civilian navigation receivers only use the C/A code on the L1 frequency. Each signal from each satellite contains a repeating message, indicating the position and orbital parameters of itself and the other satellites (almanac), a bill of health for the satellites (health bit), and the precise atomic time.

The receiver measures the time required for the signal to travel from the satellite to the receiver, by knowing the time that the signal left the satellite, and observing the time it receives the signal, based on its internal clock. If the receiver had a perfect clock, exactly in sync with those on the satellites, three measurements, from three satellites, would be sufficient to determine position in three dimensions via triangulation. However, that is not the case, so a fourth satellite is needed to resolve the receiver clock error. With four satellites, a GPS receiver can provide very accurate clock (time, date) and position information (latitude, longitude, altitude, speed, travel direction/heading).

Note that position data and accuracy are affected or degraded by the satellite geometry, electromagnetic interference, and multipath, an unpredictable set of reflections and/or direct waves each with its own degree of attenuation and delay. Primarily due to satellite geometry, measuring

altitude using GPS may introduce an accuracy error of 1.5 times the receiver's position accuracy (in the case of our GPS Receiver Module, this corresponds to about +/-20 meters in the vertical direction).

GPS signals work in the microwave radio band. They can pass through glass, but are absorbed by water molecules (wood, heavy foliage) and reflect off concrete, steel, and rock. This means that GPS units have trouble operating in rain forests, urban jungles, deep canyons, inside automobiles and boats, and in heavy snowfall - among other things. These environmental obstacles degrade positional accuracy or make it impossible to get a fix on your location.

Most GPS receivers output a stream of data so that it can be used and interpreted by other devices. The most common format (and used by our GPS Receiver Module in "Raw Mode") is NMEA0183 (National Marine Electronics Association, <http://www.nmea.org/>), developed for data communications between marine instruments. Some receivers also have proprietary data formats which are used (in the case of navigation receivers) to transfer waypoint lists, track logs, and other data between the GPS and a computer. Such proprietary formats are not covered by the NMEA standard.

The NMEA0183 is provided as a series of comma-delimited ASCII strings, each preceded with an identifying header. The data is transmitted as a 4800bps string of 8-bit ASCII characters. Thus, any microcontroller with a serial port can extract data from a GPS module. But, modules do not produce "plain text" location information. Instead, they create standardized "sentences," such as:

```
$GPGGA,170834,4124.8963,N,08151.6838,W,1,05,1.5,280.2,M,-34.0,M,,,*75
$GPGSA,A,3,19,28,14,18,27,22,31,39,,,,,1.7,1.0,1.3*34
$GPGSV,3,2,11,14,25,170,00,16,57,208,39,18,67,296,40,19,40,246,00*74
$GPRMC,220516,A,5133.82,N,00042.24,W,173.8,231.8,130694,004.2,W*70
```

Programmers can parse these strings to obtain their desired information, including time, date, latitude, longitude, speed, and altitude. For more information on NMEA0183 sentence information, visit <http://home.mira.net/~gnb/gps/nmea.html>.

The "Smart Mode" of the Parallax GPS Receiver Module will receive commands from the user and automatically parse the necessary NMEA0183 strings to calculate the desired information for the user. Using the example code provided at the end of this document will output parsed data in the following format (this screenshot was taken while driving through Lone Pine, California):

Parallax GPS Receiver Module Test Application

```
-----
Hardware Version: 1.0
Firmware Version: 1.0

Signal Valid: Yes
Acquired Satellites: 8

Local Time: 23:28:45
Local Date: 09 MAR 2006

Latitude: 036° 35' 55.3" N ( 36.5986 )
Longitude: 118° 03' 35.6" W (-118.0599 )
Altitude: 1143.2 meters ( 3750.6 feet )
Speed: 33.8 Knots ( 38.8 MPH )
Direction of Travel: 338.1°
```

There are three standard notations for displaying longitude and latitude data:

- **GPS Coordinates** (degrees, minutes, and fractional minutes), ex: 36 degrees, 35.9159 minutes
- **DDMMSS** (degrees, minutes, seconds), ex: 36 degrees, 35 minutes, 55.3 seconds
- **Decimal Degrees**, ex: 36.5986 degrees

In "Smart Mode," the Parallax GPS Receiver Module transmits latitude and longitude data to the user in GPS Coordinate format (degrees, minutes, and fractional minutes, see the "Communication Protocol" section for more details). Conversion to the two other notations, DDMMSS (degrees, minutes, second) and Decimal Degrees, is trivial and demonstrated in the example code below.

To graphically display your GPS position using Google Maps (in map, satellite, or hybrid view), simply go to <http://maps.google.com/> and enter in your decimal coordinates in the "Search" field (for example, "36.5986, -118.0599" without the quotes).

To graphically display a track or series of waypoints, GPS Visualizer (<http://www.gpsvisualizer.com/>) is a free, easy-to-use online utility that creates maps and profiles from GPS data. GPS Visualizer can read data files from many different sources, including raw NMEA strings (such as those captured directly from the Parallax GPS Receiver Module in "Raw Mode") or tab-delimited or comma-separated text of relevant GPS data.

Some additional resources and articles on GPS can be found here:

'
' -----[ Program Description ]-----
'
' This program demonstrates the capabilities of the Parallax GPS Receiver
' Module.
'
' Before running this demo, ensure that the /RAW pin is left unconnected
' or pulled HIGH to enable "smart" mode, in which the GPS Receiver Module
' will accept commands and return the requested GPS data.
'
' For an application that requires constant monitoring of multiple GPS
' data components, it is recommended to use the "raw" mode of the GPS
' Receiver Module by pulling the /RAW Pin LOW. In this mode, the module
' will transmit a constant stream of raw NMEA0183 data strings, which can

```

Parallax GPS Receiver Module \* Revision 1.1

' then be parsed by the host application.
