Features

- **Minimal External Circuitry Requirements, No RF Components on the PC Board Except Matching to the Receiver Antenna**
- **High Sensitivity, Especially at Low Data Rates**
- **Sensitivity Reduction Possible Even While Receiving**
- **Fully Integrated VCO**
- **Low Power Consumption Due to Configurable Self Polling with a Programmable Time Frame Check**
- **Supply Voltage 4.5V to 5.5V**
- **Operating Temperature Range –40°C to +105°C**
- **Single-ended RF Input for Easy Adaptation to λ / 4 Antenna or Printed Antenna on PCB**
- **Low-cost Solution Due to High Integration Level**
- **ESD Protection According to MIL-STD. 883 (4 KV HBM) Except Pin POUT (2 KV HBM)**
- **High Image Frequency Suppression due to 1 MHz IF in Conjunction with a SAW Front-end Filter**
  - **Up to 40 dB is Thereby Achievable with Newer SAWs**
- **Programmable Output Port for Sensitivity Selection or for Controlling External Periphery**
- **Communication to the Microcontroller Possible via a Single, Bi-directional Data Line**
- **Power Management (Polling) is also Possible by Means of a Separate Pin via the Microcontroller**
- **2 Different IF Bandwidth Versions are Available (300 kHz and 600 kHz)**

UHF ASK Receiver IC

ATA3741

1. Description

The ATA3741 is a multi-chip PLL receiver device supplied in an SO20 package. It has been specially developed for the demands of RF low-cost data transmission systems with low data rates from 1 kBaud to 10 kBaud (1 kBaud to 3.2 kBaud for FSK) in Manchester or Bi-phase code. The receiver is well-suited to operate with Atmel's PLL RF transmitter U2741B. Its main applications are in the areas of telemetering, security technology, and keyless-entry systems. It can be used in the frequency receiving range of f_0 = 300 MHz to 450 MHz for ASK or FSK data transmission. All the statements made below refer to 433.92-MHz and 315-MHz applications.

2. Pin Configuration

Figure 2-1. Pinning SO20

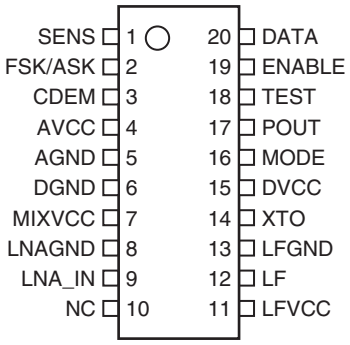

Table 2-1. Pin Description

Pin	Symbol	Function
1	SENS	Sensitivity-control resistor
2	FSK/ASK	Selecting FSK/ASK. Low: FSK, High: ASK
3	CDEM	Lower cut-off frequency data filter
4	AVCC	Analog power supply
5	AGND	Analog ground
6	DGND	Digital ground
7	MIXVCC	Power supply mixer
8	LNAGND	High-frequency ground LNA and mixer
9	LNA_IN	RF input
10	NC	Not connected
11	LFVCC	Power supply VCO
12	LF	Loop filter
13	LFGND	Ground VCO
14	XTO	Crystal oscillator
15	DVCC	Digital power supply
16	MODE	Selecting 433.92 MHz/315 MHz. Low: 4.90625 MHz (USA). High: 6.76438 (Europe)
17	POUT	Programmable output port
18	TEST	Test pin, during operation at GND
19	ENABLE	Enables the polling mode Low: polling mode off (sleep mode) High: polling mode on (active mode)
20	DATA	Data output/configuration input

3. RF Front End

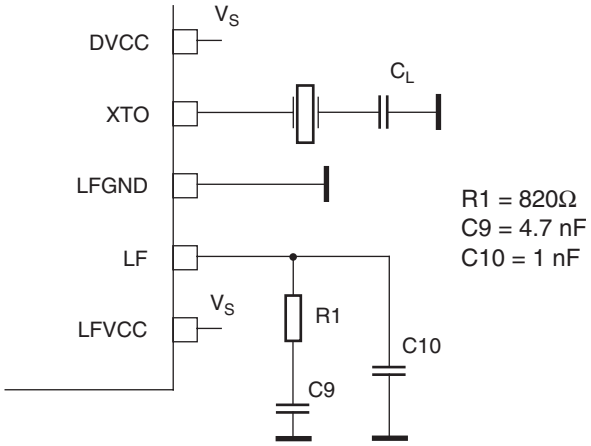
The RF front end of the receiver is a heterodyne configuration that converts the input signal into a 1-MHz IF signal. As seen in the block diagram, the front end consists of an LNA (low noise amplifier), LO (local oscillator), a mixer, and an RF amplifier.

The LO generates the carrier frequency for the mixer via a PLL synthesizer. The XTO (crystal oscillator) generates the reference frequency f_{XTO}. The VCO (voltage-controlled oscillator) generates the drive voltage frequency f_{LO} for the mixer. f_{LO} is dependent on the voltage at pin LF. f_{LO} is divided by a factor of 64. The divided frequency is compared to f_{XTO} by the phase frequency detector. The current output of the phase frequency detector is connected to a passive loop filter and thereby generates the control voltage V_{LF} for the VCO. By means of that configuration, V_{LF} is controlled in a way that f_{LO} / 64 is equal to f_{XTO}. If f_{LO} is determined, f_{XTO} can be calculated using the following formula:

$$f_{XTO} = \frac{f_{LO}}{64}$$

The XTO is a one-pin oscillator that operates at the series resonance of the quartz crystal. The crystal should be connected to GND via a capacitor CL according to Figure 3-1. The value of the capacitor is recommended by the crystal supplier. The value of CL should be optimized for the individual board layout to achieve the exact value of f_{XTO} and thereby of f_{LO}. When designing the system in terms of receiving bandwidth, the accuracy of the crystal and XTO must be considered.

Figure 3-1. PLL Peripherals



The passive loop filter connected to pin LF is designed for a loop bandwidth of B_{Loop} = 100 kHz. This value for B_{Loop} exhibits the best possible noise performance of the LO. Figure 3-1 shows the appropriate loop filter components to achieve the desired loop bandwidth. If the filter components are changed for any reason, please note that the maximum capacitive load at pin LF is limited. If the capacitive load is exceeded, a bit check may no longer be possible since f_{LO} cannot settle before the bit check starts to evaluate the incoming data stream. Therefore, self polling also will not work .

f_{LO} is determined by the RF input frequency f_{RF} and the IF frequency f_{IF} using the following formula:

$$f_{LO} = f_{RF} - f_{IF}$$

To determine f_{LO}, the construction of the IF filter must be considered at this point. The nominal IF frequency is f_{IF} = 1 MHz. To achieve a good accuracy of the filter's corner frequencies, the filter is tuned by the crystal frequency f_{XTO}. This means that there is a fixed relation between f_{IF} and f_{LO} that depends on the logic level at pin mode. This is described by the following formulas:

$$\text{MODE} = 0\ (\text{USA})\ f_{IF} = \frac{f_{LO}}{314}$$

$$\text{MODE} = 1\ (\text{Europe})\ f_{IF} = \frac{f_{LO}}{432.92}$$

The relation is designed to achieve the nominal IF frequency of f_{IF} = 1 MHz for most applications. For applications where f_{RF} = 315 MHz, MODE must be set to "0". In the case of f_{RF} = 433.92 MHz, MODE must be set to "1". For other RF frequencies, f_{IF} is not equal to 1 MHz. f_{IF} is then dependent on the logical level at pin MODE and on f_{RF}. Table 3-1 summarizes the different conditions.

The RF input either from an antenna or from a generator must be transformed to the RF input pin LNA_IN. The input impedance of LNA_IN is specified in "Electrical Characteristics" on page 23. The parasitic board inductances and capacitances also influence the input matching. The RF receiver ATA3741 exhibits its highest sensitivity at the best signal-to-noise ratio in the LNA. Hence, noise matching is the best choice for designing the transformation network.

A good practice when designing the network is to start with power matching. From that starting point, the values of the components can be varied to some extent to achieve the best sensitivity.

If a SAW is implemented into the input network, a mirror frequency suppression of ΔP_{Ref} = 40 dB can be achieved. There are SAWs available that exhibit a notch at Δf = 2 MHz. These SAWs work best for an intermediate frequency of IF = 1 MHz. The selectivity of the receiver is also improved by using a SAW. In typical automotive applications, a SAW is used.

Figure 3-2 on page 6 shows a typical input matching network for f_{RF} = 315 MHz and f_{RF} = 433.92 MHz using a SAW. Figure 3-3 on page 6 illustrates an input matching to 50Ω without a SAW. The input matching networks shown in Figure 3-3 are the reference networks for the parameters given in the "Electrical Characteristics" on page 23.

Table 3-1. Calculation of LO and IF Frequency

Conditions	Local Oscillator Frequency	Intermediate Frequency
f_{RF} = 315 MHz, MODE = 0	f_{LO} = 314 MHz	f_{IF} = 1 MHz
f_{RF} = 433.92 MHz, MODE = 1	f_{LO} = 432.92 MHz	f_{IF} = 1 MHz
300 MHz < f_{RF} < 365 MHz, MODE = 0	$f_{LO} = \frac{f_{RF}}{1 + \frac{1}{314}}$	$f_{IF} = \frac{f_{LO}}{314}$
365 MHz < f_{RF} < 450 MHz, MODE = 1	$f_{LO} = \frac{f_{RF}}{1 + \frac{1}{432.92}}$	$f_{IF} = \frac{f_{LO}}{432.92}$

Figure 3-2. Input Matching Network With SAW Filter

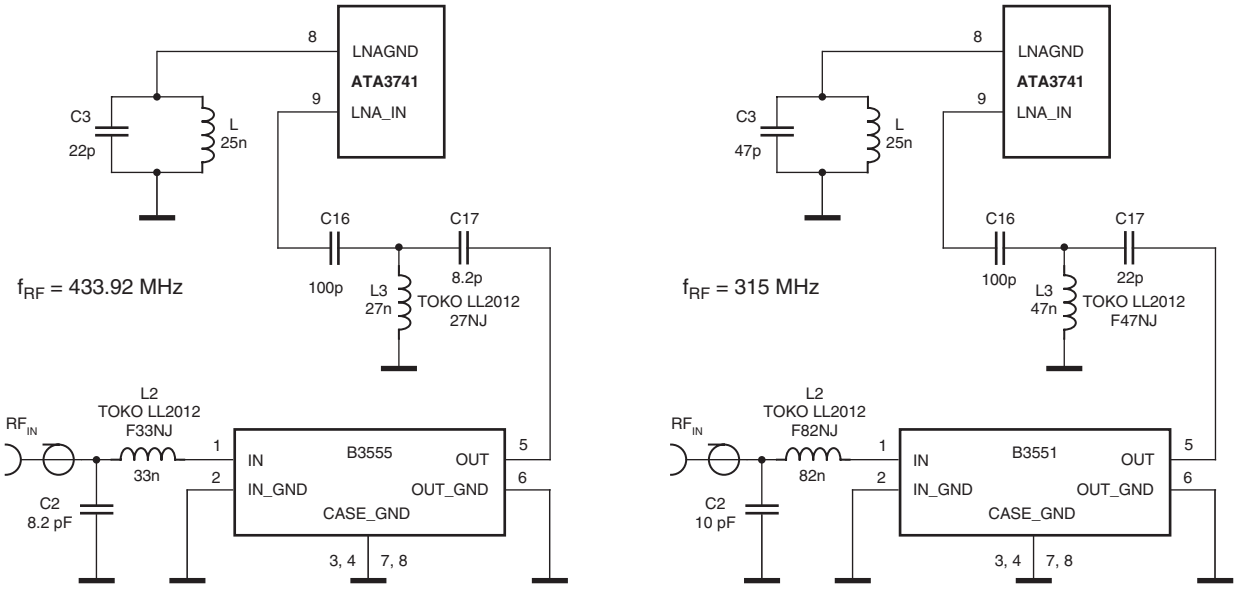


Figure 3-3. Input Matching Network Without SAW Filter

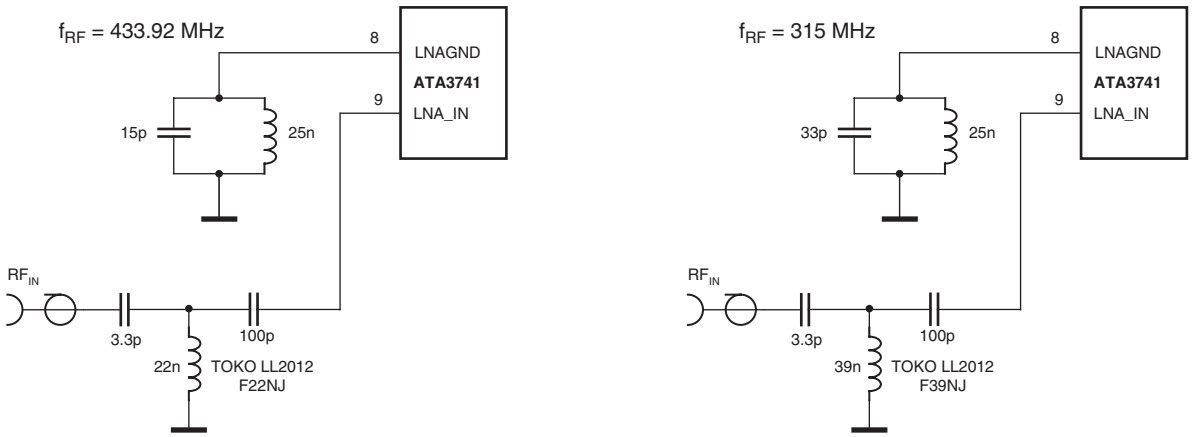


Please note that for all coupling conditions (Figure 3-2 and Figure 3-3), the bond wire inductivity of the LNA ground is compensated. C3 forms a series resonance circuit together with the bond wire. L = 25 nH is a feed inductor to establish a DC path. Its value is not critical but must be large enough not to detune the series resonance circuit. For cost reduction, this inductor can be easily printed on the PCB. This configuration improves the sensitivity of the receiver by about 1 dB to 2 dB.

4. Analog Signal Processing

4.1 IF Amplifier

The signals coming from the RF front end are filtered by the fully integrated 4th-order IF filter. The IF center frequency is f_{IF} = 1 MHz for applications where f_{RF} = 315 MHz or f_{RF} = 433.92 MHz is used. For other RF input frequencies, refer to Table 3-1 on page 5 to determine the center frequency.

The ATA3741 is available with 2 different IF bandwidths. ATA3741-M2, the version with B_{IF} = 300 kHz, is well suited for ASK systems where Atmel's PLL transmitter U2741B is used. The receiver ATA3741-M3 employs an IF bandwidth of B_{IF} = 600 kHz. This version can be used together with the U2741B in FSK and ASK mode. If used in ASK applications, it allows higher tolerances for the receiver and PLL transmitter crystals. SAW transmitters exhibit much higher transmit frequency tolerances compared to PLL transmitters. Generally, it is necessary to use B_{IF} = 600 kHz together with such transmitters.

4.2 RSSI Amplifier

The subsequent RSSI amplifier enhances the output signal of the IF amplifier before it is fed into the demodulator. The dynamic range of this amplifier is DR_{RSSI} = 60 dB. If the RSSI amplifier is operated within its linear range, the best signal-to-noise ratio (SNR) is maintained in ASK mode. If the dynamic range is exceeded by the transmitter signal, the SNR is defined by the ratio of the maximum RSSI output voltage and the RSSI output voltage due to a disturber. The dynamic range of the RSSI amplifier is exceeded if the RF input signal is about 60 dB higher compared to the RF input signal at full sensitivity.

In FSK mode, the SNR is not affected by the dynamic range of the RSSI amplifier.

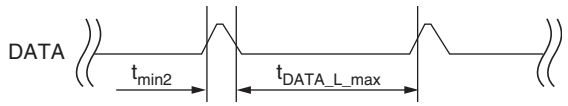
The output voltage of the RSSI amplifier is internally compared to a threshold voltage V_{Th_red}. V_{Th_red} is determined by the value of the external resistor R_{Sense}. R_{Sense} is connected between pin SENS and GND or VS. The output of the comparator is fed into the digital control logic. This makes it possible to operate the receiver at lower sensitivity.

If R_{Sense} is connected to VS, the receiver operates at a lower sensitivity. The reduced sensitivity is defined by the value of R_{Sense}, the maximum sensitivity by the SNR of the LNA input. The reduced sensitivity is dependent on the signal strength at the output of the RSSI amplifier.

Since different RF input networks may exhibit slightly different values for the LNA gain, the sensitivity values given in the electrical characteristics refer to a specific input matching. This matching is illustrated in Figure 3-3 on page 6 and exhibits the best possible sensitivity.

R_{Sense} can be connected to VS or GND via a microcontroller or by the digital output port POUT of the ATA3741 receiver IC. The receiver can be switched from full sensitivity to reduced sensitivity or vice versa at any time. In polling mode, the receiver will not wake up if the RF input signal does not exceed the selected sensitivity. If the receiver is already active, the data stream at pin DATA will disappear when the input signal is lower than defined by the reduced sensitivity. Instead of the data stream, the pattern shown in Figure 4-1 is issued at pin DATA to indicate that the receiver is still active.

Figure 4-1. Steady L State Limited DATA Output Pattern



4.3 FSK/ASK Demodulator and Data Filter

The signal coming from the RSSI amplifier is converted into the raw data signal by the ASK/FSK demodulator. The operating mode of the demodulator is set via pin ASK/FSK. Logic “L” sets the demodulator to FSK, Logic “H” sets it into ASK mode.

In ASK mode an automatic threshold control circuit (ATC) is employed to set the detection reference voltage to a value where a good SNR is achieved. This circuit also implies the effective suppression of any kind of in-band noise signals or competing transmitters. If the SNR exceeds 10 dB, the data signal can be detected properly.

The FSK demodulator is intended to be used for an FSK deviation of $\Delta f \geq 20$ kHz. Lower values may be used, but the sensitivity of the receiver will be reduced. The minimum usable deviation is dependent on the selected baud rate. In FSK mode, only BR_Range0 and BR_Range1 are available. In FSK mode, the data signal can be detected if the SNR exceeds 2 dB.

The output signal of the demodulator is filtered by the data filter before it is fed into the digital signal processing circuit. The data filter improves the SNR as its bandpass can be adopted to the characteristics of the data signal. The data filter consists of a 1st-order high-pass filter and a 1st-order low-pass filter.

The high-pass filter cut-off frequency is defined by an external capacitor connected to pin CDEM. The cut-off frequency of the high-pass filter is defined by the following formula:

$$f_{cu\_DF} = \frac{1}{2 \times \pi \times 30\ k\Omega \times CDEM}$$

In self-polling mode, the data filter must settle very rapidly to achieve a low current consumption. Therefore, CDEM cannot be increased to very high values if self-polling is used. On the other hand, CDEM must be large enough to meet the data filter requirements according to the data signal. Recommended values for CDEM are given in the “Electrical Characteristics” on page 23. The values are slightly different for ASK and FSK mode.

The cut-off frequency of the low-pass filter is defined by the selected baud rate range (BR_Range). BR_Range is defined in the OPMODE register (Section “Configuration of the Receiver” on page 17). BR_Range must be set in accordance to the used baud rate.

The ATA3741 is designed to operate with data coding where the DC level of the data signal is 50%. This is valid for Manchester and Bi-phase coding. If other modulation schemes are used, the DC level should always remain within the range of VDC_min = 33% and VDC_max = 66%. The sensitivity may be reduced by up to 1.5 dB in that condition.

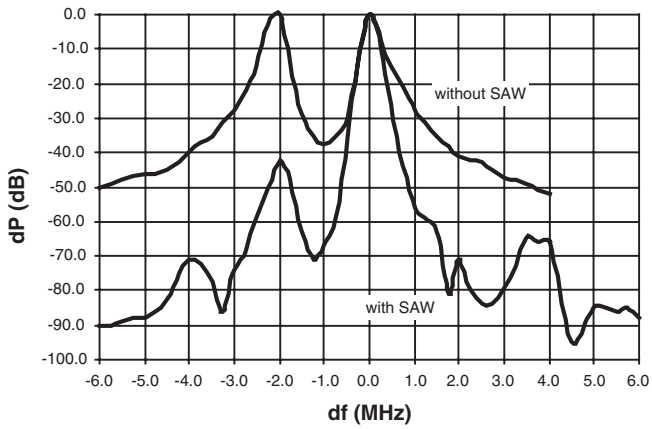
Each BR_Range is also defined by a minimum and a maximum edge-to-edge time (t_{ee_sig}). These limits are defined in the “Electrical Characteristics” on page 23. They should not be exceeded to maintain full sensitivity of the receiver.

4.4 Receiving Characteristics

The RF receiver ATA3741 can be operated with and without a SAW front-end filter. In a typical automotive application, a SAW filter is used to achieve better selectivity. The selectivity with and without a SAW front-end filter is illustrated in Figure 4-2 on page 9. This example relates to ASK mode and the 300-kHz bandwidth version of the ATA3741. FSK mode and the 600-kHz version of the receiver exhibit similar behavior. Note that the mirror frequency is reduced by 40 dB. The plots are printed relative to the maximum sensitivity. If a SAW filter is used, an insertion loss of about 4 dB must be considered.

When designing the system in terms of receiving bandwidth, the LO deviation must be considered as it also determines the IF center frequency. The total LO deviation is calculated to be the sum of the deviation of the crystal and the XTO deviation of the ATA3741. Low-cost crystals are specified to be within ±100 ppm. The XTO deviation of the ATA3741 is an additional deviation due to the XTO circuit. This deviation is specified to be ±30 ppm. If a crystal of ±100 ppm is used, the total deviation is ±130 ppm in that case. Note that the receiving bandwidth and the IF-filter bandwidth are equivalent in ASK mode but not in FSK mode.

Figure 4-2. Receiving Frequency Response



5. Polling Circuit and Control Logic

The receiver is designed to consume less than 1 mA while being sensitive to signals from a corresponding transmitter. This is achieved via the polling circuit. This circuit enables the signal path periodically for a short time. During this time the bit-check logic verifies the presence of a valid transmitter signal. Only if a valid signal is detected does the receiver remain active and transfer the data to the connected microcontroller. If there is no valid signal present, the receiver is in sleep mode most of the time, resulting in low current consumption. This condition is called polling mode. A connected microcontroller is disabled during that time.

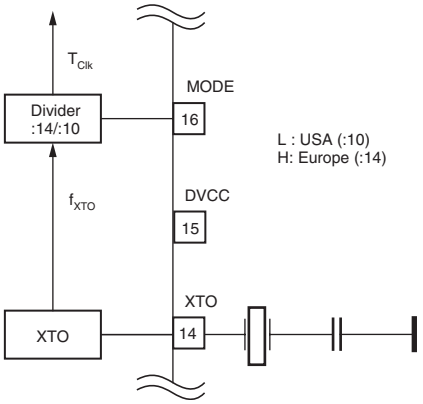
All relevant parameters of the polling logic can be configured by the connected microcontroller. This flexibility enables the user to meet the specifications in terms of current consumption, system response time, data rate, etc.

Regarding the number of connection wires to the microcontroller, the receiver is very flexible. It can be either operated by a single bi-directional line to save ports to the connected microcontroller, or it can be operated by up to three uni-directional ports.

5.1 Basic Clock Cycle of the Digital Circuitry

The complete timing of the digital circuitry and the analog filtering is derived from one clock. As seen in Figure 5-1 on page 10, this clock cycle T_{Clk} is derived from the crystal oscillator (XTO) in combination with a divider. The division factor is controlled by the logical state at pin MODE. The frequency of the crystal oscillator (f_{XTO}) is defined by the RF input signal (f_{RFin}) which also defines the operating frequency of the local oscillator (f_{LO}) (See "RF Front End" on page 4).

Figure 5-1. Generation of the Basic Clock Cycle



Pin MODE can now be set in accordance with the desired clock cycle T_{Clk}. T_{Clk} controls the following application-relevant parameters:

- Timing of the polling circuit including bit check
- Timing of analog and digital signal processing
- Timing of register programming
- Frequency of the reset marker
- IF filter center frequency (f_{IF0})

Most applications are dominated by two transmission frequencies: f_{Send} = 315 MHz is mainly used in the USA, f_{Send} = 433.92 MHz in Europe. In order to ease the usage of all T_{Clk}-dependent parameters, the electrical characteristics display three conditions for each parameter.

- USA Applications
  (f_{XTO} = 4.90625 MHz, MODE = 0, T_{Clk} = 2.0383 µs)
- Europe Applications
  (f_{XTO} = 6.76438 MHz, MODE = 1, T_{Clk} = 2.0697 µs)
- Other applications
  (T_{Clk} is dependent on f_{XTO} and on the logical state of pin MODE. The electrical characteristic is given as a function of T_{Clk}).

The clock cycle of some function blocks depends on the selected baud rate range (BR_Range) which is defined in the OPMODE register. This clock cycle T_{XClk} is defined by the following formulas for further reference:

BR_Range =	BR_Range0:	$T_{XClk} = 8 \times T_{Clk}$
	BR_Range1:	$T_{XClk} = 4 \times T_{Clk}$
	BR_Range2:	$T_{XClk} = 2 \times T_{Clk}$
	BR_Range3:	$T_{XClk} = 1 \times T_{Clk}$

5.2 Polling Mode

As shown in Figure 3-2 on page 6, the receiver stays in polling mode in a continuous cycle of three different modes. In sleep mode, the signal processing circuitry is disabled for the time period T_{Sleep} while consuming a low current of $I_S = I_{Soff}$. During the start-up period, $T_{Startup}$, all signal processing circuits are enabled and settled. In the following bit-check mode, the incoming data stream is analyzed bit by bit against a valid transmitter signal. If no valid signal is present, the receiver is set back to sleep mode after the period $T_{Bitcheck}$. This period varies check by check as it is a statistical process. An average value for $T_{Bitcheck}$ is given in "Electrical Characteristics" on page 23. During $T_{Startup}$ and $T_{Bitcheck}$ the current consumption is $I_S = I_{Son}$. The average current consumption in polling mode is dependent on the duty cycle of the active mode and can be calculated as:

$$I_{Spoll} = \frac{I_{Soff} \times T_{Sleep} + I_{Son} \times (T_{Startup} + T_{Bitcheck})}{T_{Sleep} + T_{Startup} + T_{Bitcheck}}$$

During T_{Sleep} and $T_{Startup}$, the receiver is not sensitive to a transmitter signal. To guarantee the reception of a transmitted command, the transmitter must start the telegram with an adequate preburst. The required length of the preburst is dependent on the polling parameters T_{Sleep}, $T_{Startup}$, $T_{Bitcheck}$, and the startup time of a connected microcontroller ($T_{Start\_\mu C}$). $T_{Bitcheck}$ thus depends on the actual bit rate and the number of bits ($N_{Bitcheck}$) to be tested.

The following formula indicates how to calculate the preburst length.

$$T_{Preburst} \geq T_{Sleep} + T_{Startup} + T_{Bitcheck} + T_{Start\_\mu C}$$

5.2.1 Sleep Mode

The length of period T_{Sleep} is defined by the 5-bit word Sleep of the OPMODE register, on the extension factor X_{Sleep} according to Figure 5-4 on page 13, and on the basic clock cycle T_{Clk}. It is calculated to be:

$$T_{Sleep} = Sleep \times X_{Sleep} \times 1024 \times T_{Clk}$$

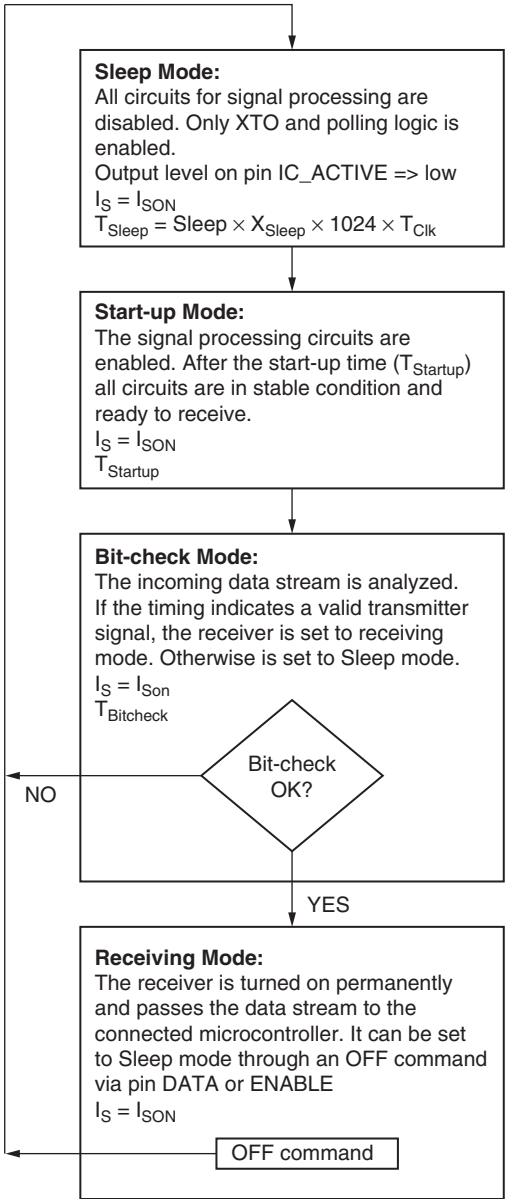
In US and European applications, the maximum value of T_{Sleep} is about 60 ms if X_{Sleep} is set to 1. The time resolution is about 2 ms in that case. The sleep time can be extended to almost half a second by setting X_{Sleep} to 8. X_{Sleep} can be set to 8 by bit $X_{SleepStd}$ or by bit $X_{SleepTemp}$, resulting in a different mode of action as described below:

$X_{SleepStd}$ = 1 implies the standard extension factor. The sleep time is always extended.

$X_{SleepTemp}$ = 1 implies the temporary extension factor. The extended sleep time is used as long as every bit check is OK. If the bit check fails once, this bit is set back to 0 automatically, resulting in a regular sleep time. This functionality can be used to save current in the presence of a modulated disturber similar to an expected transmitter signal. The connected microcontroller is rarely activated in that condition. If the disturber disappears, the receiver switches back to regular polling and is again sensitive to appropriate transmitter signals.

As seen in Table 5-6 on page 19, the highest register value of Sleep sets the receiver to a permanent sleep condition. The receiver remains in that condition until another value for Sleep is programmed into the OPMODE register. This function is desirable where several devices share a single data line.

Figure 5-2. Polling Mode Flow Chart



Sleep: 5-bit word defined by Sleep0 to Sleep4 in OPMODE register

X_{Sleep}: Extension factor defined by $X_{SleepTemp}$ according to Table 5-7

T_{Clk}: Basic clock cycle defined by f_{XTO} and pin MODE

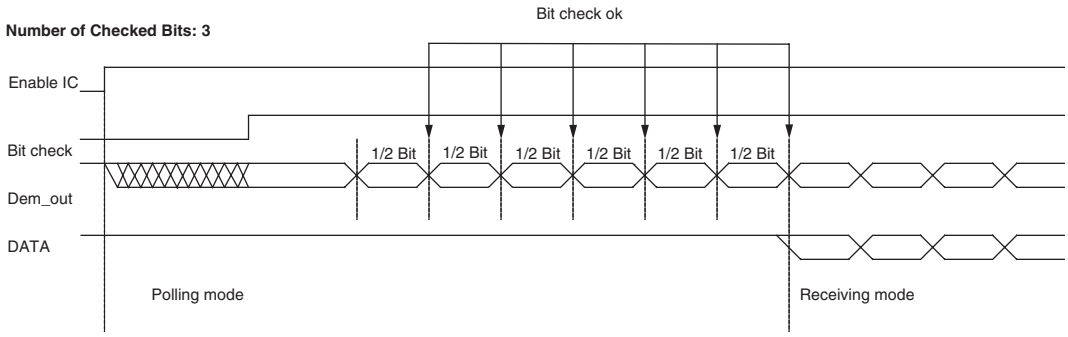
$T_{Startup}$: Is defined by the selected baud rate range and T_{Clk}. The baud rate range is defined by Baud0 and Baud1 in the OPMODE register.

$T_{Bitcheck}$: Depends on the result of the bit check.

If the bit check is ok, $T_{Bitcheck}$ depends on the number of bits to be checked ($N_{Bitchecked}$) and on the utilized data rate.

If the bit check fails, the average time period for that check depends on the selected baud rate range on T_{Clk}. The baud rate range is defined by Baud0 and Baud1 in the OPMODE register.

Figure 5-3. Timing Diagram for a Completely Successful Bit Check



5.3 Bit-check Mode

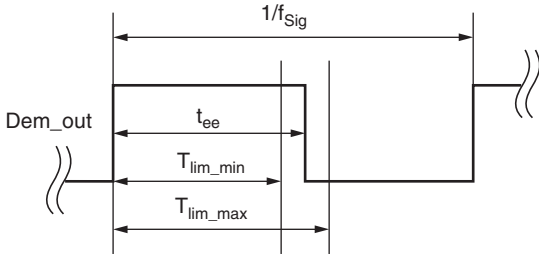
In bit-check mode, the incoming data stream is examined to distinguish between a valid signal from a corresponding transmitter and signals due to noise. This is done by subsequent time frame checks where the distances between 2 signal edges are continuously compared to a programmable time window. The maximum count of this edge-to-edge test, before the receiver switches to receiving mode, is also programmable.

5.3.1 Configuring the Bit Check

Assuming a modulation scheme that contains 2 edges per bit, two time frame checks verify one bit. This is valid for Manchester, Bi-phase and most other modulation schemes. The maximum count of bits to be checked can be set to 0, 3, 6 or 9 bits via the variable $N_{Bitcheck}$ in the OPMODE register. This implies 0, 6, 12 and 18 edge-to-edge checks respectively. If $N_{Bitcheck}$ is set to a higher value, the receiver is less likely to switch to the receiving mode due to noise. In the presence of a valid transmitter signal, the bit check takes less time if $N_{Bitcheck}$ is set to a lower value. In polling mode, the bit-check time is not dependent on $N_{Bitcheck}$. Figure 5-3 on page 12 shows an example where 3 bits are tested successfully and the data signal is transferred to pin DATA.

Figure 5-4 shows how the time window for the bit check is defined by two separate time limits. If the edge-to-edge time t_{ee} is in between the lower bit check limit T_{Lim_min} and the upper bit check limit T_{Lim_max}, the check will be continued. If t_{ee} is smaller than T_{Lim_min} or t_{ee} exceeds T_{Lim_max}, the bit check will be terminated and the receiver will switch to sleep mode.

Figure 5-4. Valid Time Window for Bit Check



For best noise immunity it is recommended to use a low span between T_{Lim_min} and T_{Lim_max}. This is achieved using a fixed frequency at a 50% duty cycle for the transmitter preburst. A “11111...” or a “10101...” sequence in Manchester or Bi-phase is a good choice in this regard. A good compromise between receiver sensitivity and susceptibility to noise is a time window of ±25% regarding the expected edge-to-edge time t_{ee}. Using preburst patterns that contain various edge-to-edge time periods, the bit check limits must be programmed according to the required span.

The bit-check limits are determined by means of the formula below:

$T_{Lim\_min} = Lim\_min \times T_{XClk}$
$T_{Lim\_max} = (Lim\_max - 1) \times T_{XClk}$

Lim_min and Lim_max are defined by a 5-bit word each within the LIMIT register.

Using the above formulas, Lim_min and Lim_max can be determined according to the required T_{Lim_min}, T_{Lim_max} and T_{XClk}. The time resolution when defining T_{Lim_min} and T_{Lim_max} is T_{XClk}. The minimum edge-to-edge time t_{ee} ($t_{DATA\_L\_min}$, $t_{DATA\_H\_min}$) is defined in Section “Receiving Mode” on page 15. Due to this, the lower limit should be set to Lim_min ≥ 10. The maximum value of the upper limit is Lim_max = 63.

Figure 5-5, Figure 5-6 and Figure 5-7 illustrate the bit check for the default bit-check limits Lim_min = 14 and Lim_max = 24. When the IC is enabled, the signal processing circuits are enabled during $T_{Startup}$. The output of the ASK/FSK demodulator (Dem_out) is undefined during that period. When the bit check becomes active, the bit-check counter is clocked with the cycle T_{XClk}.

Figure 5-5 shows how the bit check proceeds if the bit-check counter value CV_Lim is within the limits defined by Lim_min and Lim_max at the occurrence of a signal edge. In Figure 5-6, the bit check fails as the value CV_lim is lower than the limit Lim_min. The bit check also fails if CV_Lim reaches Lim_max. This is illustrated in Figure 5-7.

Figure 5-5. Timing Diagram During Bit Check

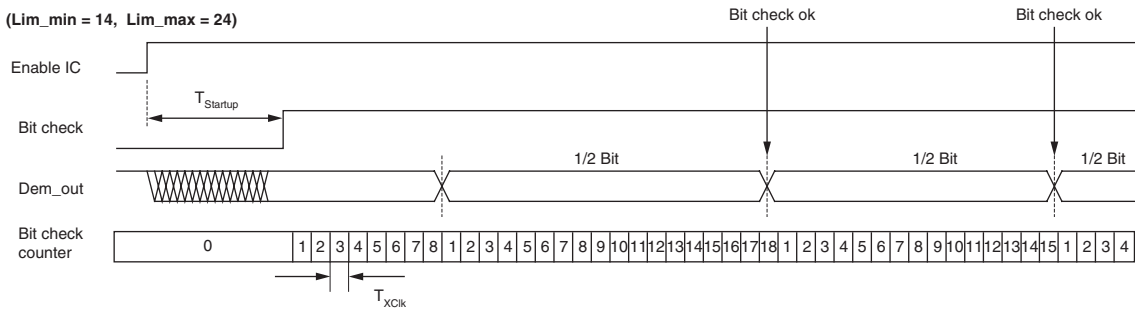


Figure 5-6. Timing Diagram for Failed Bit Check (Condition: CV_Lim < Lim_min)

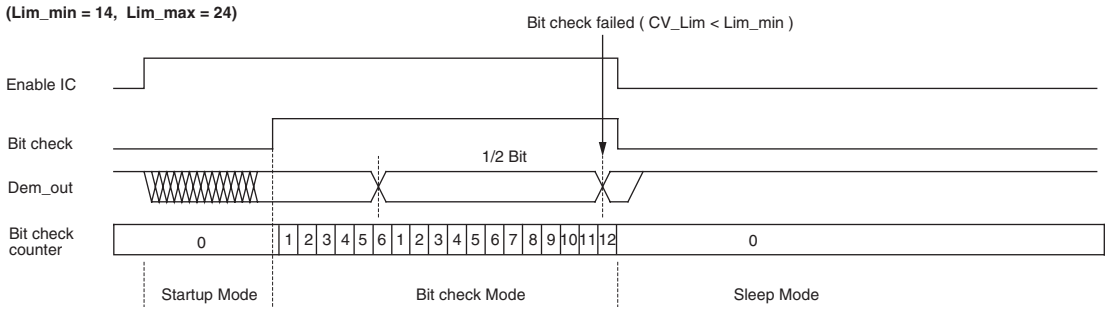

Figure 5-7. Timing Diagram for Failed Bit Check (Condition: CV_Lim ≥ Lim_max)

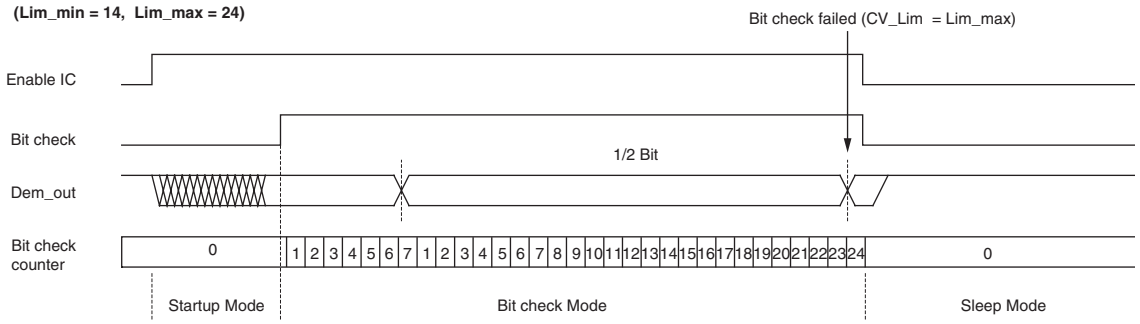

5.3.2 Duration of the Bit Check

If no transmitter signal is present during the bit check, the output of the ASK/FSK demodulator delivers random signals. The bit check is a statistical process and $T_{Bitcheck}$ varies for each check. Therefore, an average value for $T_{Bitcheck}$ is given in “Electrical Characteristics”. $T_{Bitcheck}$ depends on the selected baud rate range and on T_{Clk}. A higher baud rate range causes a lower value for $T_{Bitcheck}$, resulting in lower current consumption in polling mode.

In the presence of a valid transmitter signal, $T_{Bitcheck}$ is dependent on the frequency of that signal, on f_{Sig}, and on the count of the checked bits, $N_{Bitcheck}$. A higher value for $N_{Bitcheck}$ thereby results in a longer period for $T_{Bitcheck}$, requiring a higher value for the transmitter preburst $T_{Preburst}$.

5.4 Receiving Mode

If the bit check is successful for all bits specified by $N_{Bitcheck}$, the receiver switches to receiving mode. As seen in Figure 5-3 on page 12, the internal data signal is then switched to pin DATA. A connected microcontroller can be woken up by the negative edge at pin DATA. The receiver stays in that condition until it is explicitly switched back to polling mode.

5.4.1 Digital Signal Processing

The data from the ASK/FSK demodulator (Dem_out) is digitally processed in different ways and as a result converted into the output signal data. This processing depends on the selected baud rate range (BR_Range). Figure 5-8 illustrates how Dem_out is synchronized by the extended clock cycle T_{XClk}. This clock is also used for the bit-check counter. Data can change its state only after T_{XClk} elapsed. The edge-to-edge time period t_{ee} of the Data signal, as a result, is always an integral multiple of T_{XClk}.

The minimum time period between two edges of the data signal is limited to $t_{ee} \geq T_{DATA\_min}$. This implies an efficient suppression of spikes at the DATA output. At the same time, it limits the maximum frequency of edges at DATA. This eases the interrupt handling of a connected microcontroller. T_{DATA_min} is to some extent affected by the preceding edge-to-edge time interval t_{ee} as illustrated in Figure 5-9 on page 16. If t_{ee} is in between the specified bit-check limits, the following level is frozen for the time period T_{DATA_min} = tmin1; if t_{ee} is outside that bit check limit, T_{DATA_min} = tmin2 is the relevant stable time period.

The maximum time period for DATA to be low is limited to $T_{DATA\_L\_max}$. This function ensures a finite response time during programming or switching off the receiver via pin DATA. $T_{DATA\_L\_max}$ is thereby longer than the maximum time period indicated by the transmitter data stream. Figure 5-10 on page 16 gives an example where Dem_out remains low after the receiver has switched to receiving mode.

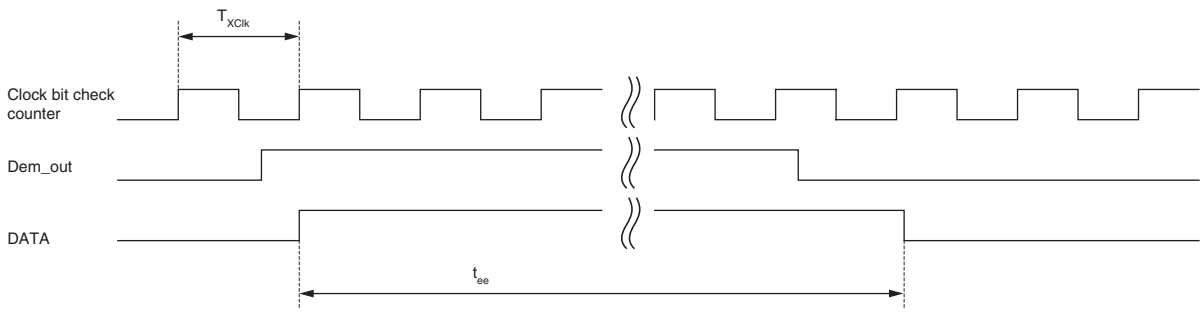

Figure 5-9. Debouncing of the Demodulator Output

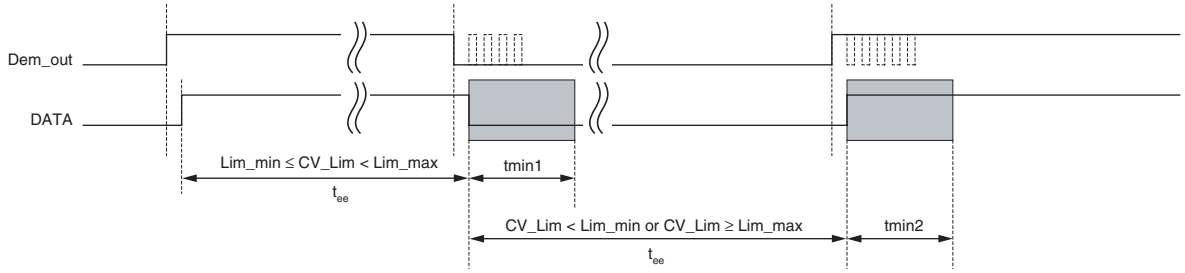

Figure 5-10. Steady L State Limited DATA Output Pattern after Transmission

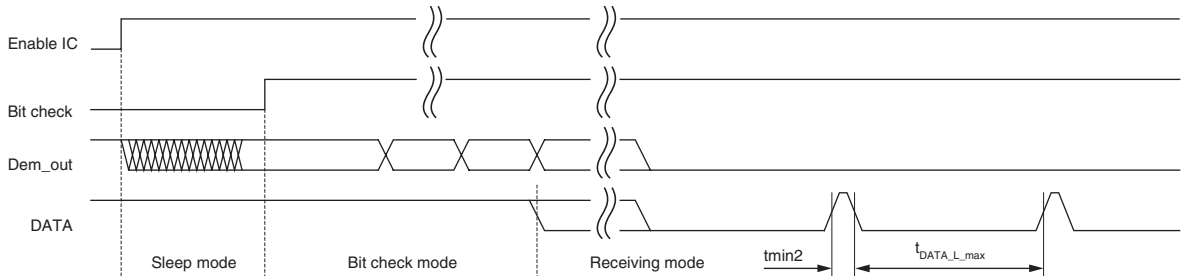

After the end of a data transmission, the receiver remains active and random noise pulses appear at pin DATA. The edge-to-edge time period t_{ee} of the majority of these noise pulses is equal to or slightly higher than T_{DATA_min}.

5.4.2 Switching the Receiver Back to Sleep Mode

The receiver can be set back to polling mode via pin DATA or via pin ENABLE.

When using pin DATA, this pin must be pulled to low by the connected microcontroller for the period t1. Figure 5-11 on page 17 illustrates the timing of the OFF command (see also Figure 5-15 on page 22). The minimum value of t1 depends on the BR_Range. The maximum value for t1 is not limited but it is recommended not to exceed the specified value to prevent erasing the reset marker. This item is explained in more detail in Section "Configuration of the Receiver" on page 17. Setting the receiver to sleep mode via DATA is achieved by programming bit 1 of the OPMODE register to 1. Only one sync pulse (t3) is issued.

The duration of the OFF command is determined by the sum of t1, t2 and t10. After the OFF command, the sleep time T_{Sleep} elapses. Note that the capacitive load at pin DATA is limited. The resulting time constant τ together with an optional external pull-up resistor may not be exceeded to ensure proper operation.

If the receiver is set to polling mode via pin ENABLE, an "L" pulse (T_{Doze}) must be issued at that pin. Figure 5-12 on page 17 illustrates the timing of that command. After the positive edge of this pulse, the sleep time T_{Sleep} elapses. The receiver remains in sleep mode as long as ENABLE is held to "L". If the receiver is polled exclusively by a microcontroller, T_{Sleep} can be programmed to "0" to enable an instantaneous response time. This command is the faster option than via pin DATA, but at the cost of an additional connection to the microcontroller.

Figure 5-11. Timing Diagram of the OFF Command Via Pin DATA

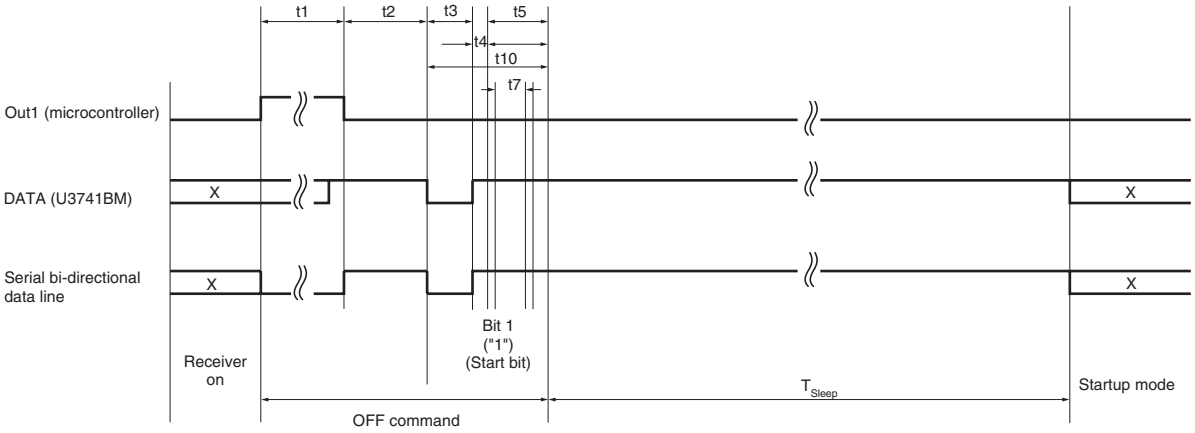

Figure 5-12. Timing Diagram of the OFF Command Via Pin ENABLE

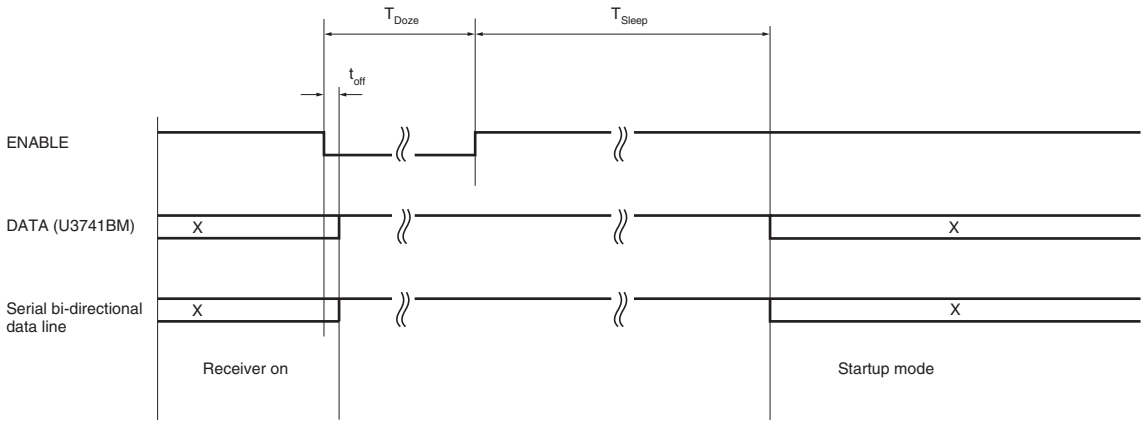

5.5 Configuration of the Receiver

The ATA3741 receiver is configured via two 12-bit RAM registers called OPMODE and LIMIT. The registers can be programmed by means of the bi-directional DATA port. If the register contents have changed due to a voltage drop, this condition is indicated by a certain output pattern called reset marker (RM). The receiver must be reprogrammed in that case. After a power-on reset (POR), the registers are set to default mode. If the receiver is operated in default mode, there is no need to program the registers.

Table 5-2 on page 18 shows the structure of the registers. As shown in Table 5-1, bit 1 defines if the receiver is set back to polling mode via the OFF command, (see Section "Receiving Mode" on page 15) or if it is programmed. Bit 2 represents the register address; it selects the appropriate register to be programmed.

Table 5-1. Effect of Bit 1 and Bit 2 in Programming the Registers

Bit 1	Bit 2	Action
1	x	The receiver is set back to polling mode (OFF command)
0	1	The OPMODE register is programmed
0	0	The LIMIT register is programmed

Table 5-3 through Table 5-9 on page 20 illustrate the effect of the individual configuration words. The default configuration is labeled for each word.

BR_Range sets the appropriate baud rate range. At the same time, it defines XLim. XLim is used to define the bit check limits T_{Lim_min} and T_{Lim_max} as shown in Table 5-3.

POUT can be used to control the sensitivity of the receiver. In that application, POUT is set to “1” to reduce the sensitivity. This implies that the receiver operates with full sensitivity after a POR.

Table 5-2. Effect of the Configuration Words within the Registers

Bit1	Bit2	Bit2	Bit4	Bit5	Bit6	Bit7	Bit8	Bit9	Bit10	Bit11	Bit12	Bit13	Bit14

5.5.1 Conservation of the Register Information

The ATA3741 has integrated power-on reset and brown-out detection circuitry to provide a mechanism to preserve the RAM register information.

Figure 5-13 on page 21 shows the timing of a power-on reset (POR) generated if the supply voltage V_S drops below the threshold voltage $V_{ThReset}$. The default parameters are programmed into the configuration registers in that condition. Once V_S exceeds $V_{ThReset}$, the POR is canceled after the minimum reset period t_{Rst}. A POR is also generated when the supply voltage of the receiver is turned on.

To indicate that condition, the receiver displays a reset marker (RM) at pin DATA after a reset. The RM is represented by the fixed frequency f_{RM} at a 50% duty cycle. RM can be canceled via an “L” pulse t1 at pin DATA. The RM implies the following characteristics:

- f_{RM} is lower than the lowest feasible frequency of a data signal. By this means, RM cannot be misinterpreted by the connected microcontroller.
- If the receiver is set back to polling mode via pin DATA, RM cannot be canceled by accident if t1 is applied according to the proposal in Section “Programming the Configuration Register” on page 21.

By means of that mechanism, the receiver cannot lose its register information without communicating that condition via the reset marker RM.

Figure 5-13. Generation of the Power-on Reset

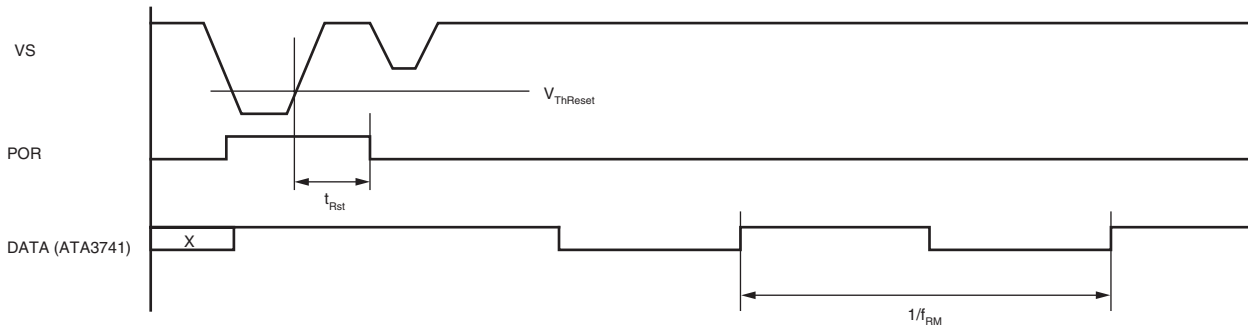

Figure 5-14. Timing of the Register Programming

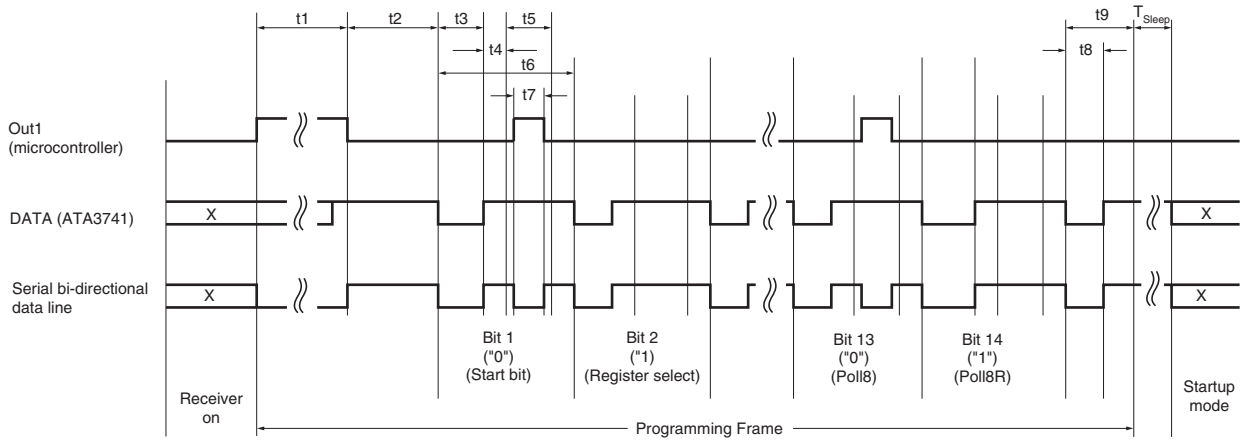
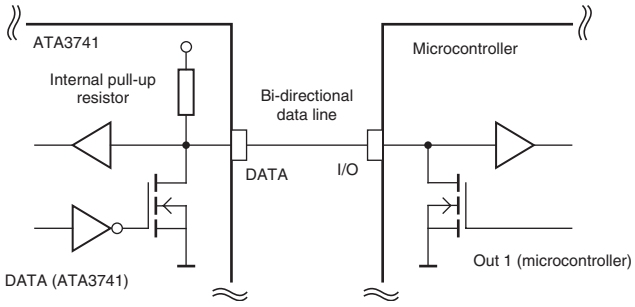


5.5.2 Programming the Configuration Register

The configuration registers are programmed serially via the bi-directional data line as shown in Figure 5-14 and Figure 5-15 on page 22.

Figure 5-15. One-wire Connection to a Microcontroller



To start programming, the serial data line DATA is pulled to “L” by the microcontroller for the time period t1. When DATA has been released, the receiver becomes the master device. When the programming delay period t2 has elapsed, it emits 14 subsequent synchronization pulses with the pulse length t3. After each of these pulses, a programming window occurs. The delay until the program window starts is determined by t4, the duration is defined by t5. Within the programming window, the individual bits are set. If the microcontroller pulls down pin DATA for the time period t7 during t5, the according bit is set to “0”. If no programming pulse t7 is issued, this bit is set to “1”. All 14 bits are subsequently programmed in this way. The time frame to program a bit is defined by t6.

Bit 14 is followed by the equivalent time window t9. During this window, the equivalent acknowledge pulse t8 (E_Ack) occurs if the mode word just programmed is equivalent to the mode word that was already stored in that register. E_Ack should be used to verify that the mode word was correctly transferred to the register. The register must be programmed twice in that case.

Programming of a register is possible both during sleep and active mode of the receiver.

During programming, the LNA, LO, low-pass filter, IF amplifier and the demodulator are disabled.

The programming start pulse t1 initiates the programming of the configuration registers. If bit 1 is set to “1”, it represents the OFF command to set the receiver back to polling mode at the same time. For the length of the programming start pulse t1, the following convention should be considered:

- $t1(min) < t1 < 1535 \times T_{Clk}$: [t1(min) is the minimum specified value for the relevant BR_Range]

Programming (or the OFF command) is initiated if the receiver is not in reset mode. If the receiver is in reset mode, programming (or the OFF command) is not initiated, and the reset marker RM is still present at pin DATA.

This period is generally used to switch the receiver to polling mode. In a reset condition, RM is not canceled by accident.

- $t1 > 5632 \times T_{Clk}$

Programming (or the OFF command) is initiated in any case. RM is cancelled if present. This period is used if the connected microcontroller detected RM. If a configuration register is programmed, this time period for t1 can generally be used.

Note that the capacitive load at pin DATA is limited. The resulting time constant t together with an optional external pull-up resistor should not be exceeded, to ensure proper operation.

6. Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Parameters	Symbol	Min.	Max.	Unit
Supply voltage	V_S		6	V

Input sensitivity ASK 600-kHz IF filter	BR_Range3		–104	–106	–108	dBm
Sensitivity variation ASK for the full operating range compared to T_{amb} = 25°C, V_S = 5V	300-kHz and 600-kHz version f_{in} = 433.92 MHz/315 MHz f_{IF} = 1 MHz $P_{ASK} = P_{Ref\_ASK} + \Delta P_{Ref}$	ΔP_{Ref}	+2.5		–1.5	dB
Sensitivity variation ASK for full operating range including IF filter compared to T_{amb} = 25°C, V_S = 5V	300-kHz version f_{in} = 433.92 MHz/315 MHz f_{IF} = 0.88 MHz to 1.12 MHz f_{IF} = 0.85 MHz to 1.15 MHz $P_{ASK} = P_{Ref\_ASK} + \Delta P_{Ref}$	ΔP_{Ref}	+5.5 +7.5		–1.5 –1.5	dB dB
Sensitivity variation ASK for full operating range including IF filter compared to T_{amb} = 25°C, V_S = 5V	600-kHz version f_{in} = 433.92 MHz/315 MHz f_{IF} = 0.79 MHz to 1.21 MHz f_{IF} = 0.73 MHz to 1.27 MHz $P_{ASK} = P_{Ref\_ASK} + \Delta P_{Ref}$	ΔP_{Ref}	+5.5 +7.5		–1.5 –1.5	dB dB
Input sensitivity FSK 600-kHz IF filter	Input matched according to Figure 3-3, BER ≤10^{-3}, B = 600 kHz f_{in} = 433.92 MHz/315 MHz T = 25°C, V_S = 5V f_{IF} = 1 MHz	P_{Ref_FSK}				
Input sensitivity FSK 600-kHz IF filter	BR_Range0 df ≥ ±20 kHz df ≥ ±30 kHz		–95.5 –96.5	–97.5 –98.5	–99.5 –100.5	dBm dBm
Input sensitivity FSK 600-kHz IF filter	BR_Range1 df ≥ ±20 kHz df ≥ ±30 kHz		–94.5 –95.5	–96.5 –97.5	–98.5 –99.5	dBm dBm
Sensitivity variation FSK for the full operating range compared to T_{amb} = 25°C, V_S = 5V	600-kHz version f_{in} = 433.92 MHz/315 MHz f_{IF} = 1 MHz $P_{FSK} = P_{Ref\_FSK} + \Delta P_{Ref}$	ΔP_{Ref}	+2.5		–1.5	dB
Sensitivity variation FSK for full operating range including IF filter compared to T_{amb} = 25°C, V_S = 5V	600-kHz version f_{in} = 433.92 MHz/315 MHz f_{IF} = 0.86 MHz to 1.14 MHz f_{IF} = 0.82 MHz to 1.18 MHz $P_{FSK} = P_{Ref\_FSK} + \Delta P_{Ref}$	ΔP_{Ref}	+5.5 +7.5		–1.5 –1.5	dB dB
FSK frequency deviation	The sensitivity of the receiver is higher for higher values of Δf_{FSK} BR_Range0 BR_Range1 BR_Range2 and BR_Range3 are not suitable for FSK operation	Δf_{FSK}	20 20	30 30	50 50	kHz kHz
SNR to suppress inband noise signals	ASK mode FSK mode	SNR_{ASK} SNR_{FSK}	10 2		12 3	dB dB
Dynamic range RSSI ampl.		ΔR_{RSSI}		60		dB

9. Electrical Characteristics (Continued)

All parameters refer to GND, T_{amb} = –40°C to +105°C, V_S = 4.5V to 5.5V, f_0 = 433.92 MHz and f_0 = 315 MHz, unless otherwise specified. (V_S = 5V, T_{amb} = 25°C)

Parameters	Test Conditions	Symbol	Min.	Typ.	Max.	Unit
Lower cut-off frequency of the data filter	$f_{cu\_DF} = \frac{1}{2 \times \pi \times 30\ k\Omega \times CDEM}$	f_{cu_DF}	0.11	0.16	0.20	kHz
Recommended CDEM for best performance	ASK mode BR_Range0 (Default) BR_Range1 BR_Range2 BR_Range3	CDEM		 39 22 12 8.2		 nF nF nF nF
Recommended CDEM for best performance	FSK mode BR_Range0 (Default) BR_Range1 BR_Range2 and BR_Range3 are not suitable for FSK operation	CDEM		 27 15		 nF nF
Maximum edge-to-edge time period of the input data signal for full sensitivity	BR_Range0 (Default) BR_Range1 BR_Range2 BR_Range3	t_{ee_sig}			1000 560 320 180	µs µs µs µs
Upper cut-off frequency data filter	Upper cut-off frequency programmable in 4 ranges via a serial mode word BR_Range0 (Default) BR_Range1 BR_Range2 BR_Range3	f_u	 2.5 4.3 7.6 13.6	 3.1 5.4 9.5 17.0	 3.7 6.5 11.4 20.4	 kHz kHz kHz kHz
Minimum edge-to-edge time period of the input data signal for full sensitivity	BR_Range0 (Default) BR_Range1 BR_Range2 BR_Range3	t_{ee_sig}			270 156 89 50	µs µs µs µs
Reduced sensitivity	R_{Sense} connected from pin SENS to V_S, input matched according to Figure 3-3	P_{Ref_Red}				dBm (peak level)
Reduced sensitivity	R_{Sense} = 56 kΩ, f_{in} = 433.92 MHz, (V_S = 5V, T_{amb} = 25°C) At B = 300 kHz At B = 600 kHz		 –71 –67	 –76 –72	 –81 –77	 dBm dBm
Reduced sensitivity	R_{Sense} = 100 kΩ, f_{in} = 433.92 MHz At B = 300 kHz At B = 600 kHz		 –80 –76	 –85 –81	 –90 –86	 dBm dBm
Reduced sensitivity	R_{Sense} = 56 kΩ, f_{in} = 315 MHz At B = 300 kHz At B = 600 kHz		 –72 –68	 –77 –73	 –82 –78	 dBm dBm
Reduced sensitivity	R_{Sense} = 100 kΩ, f_{in} = 315 MHz At B = 300 kHz At B = 600 kHz		 –81 –77	 –86 –82	 –91 –87	 dBm dBm
Reduced sensitivity variation over full operating range	R_{Sense} = 56 kΩ R_{Sense} = 100 kΩ $P_{Red} = P_{Ref\_Red} + DP_{Red}$	ΔP_{Red}	5 6	0 0	0 0	dB dB

9. Electrical Characteristics (Continued)

All parameters refer to GND, T_{amb} = –40°C to +105°C, V_S = 4.5V to 5.5V, f_0 = 433.92 MHz and f_0 = 315 MHz, unless otherwise specified. (V_S = 5V, T_{amb} = 25°C)

Parameters	Test Conditions	Symbol	Min.	Typ.	Max.	Unit
Reduced sensitivity variation for different values of R_{Sense}	Values relative to R_{Sense} = 56 kΩ R_{Sense} = 56 kΩ R_{Sense} = 68 kΩ R_{Sense} = 82 kΩ R_{Sense} = 100 kΩ R_{Sense} = 120 kΩ R_{Sense} = 150 kΩ $P_{Red} = P_{Ref\_Red} + \Delta P_{Red}$	ΔP_{Red}		0 –3.5 –6.0 –9.0 –11.0 –13.5		dB dB dB dB dB dB
Threshold voltage for reset		$V_{ThReset}$	1.95	2.8	3.75	V
Digital Ports						
Data output - Saturation voltage LOW - Internal pull-up resistor - Maximum time constant - Maximum capacitive load	 I_{ol} = 1 mA t = C_L (R_{pup}//R_{Ext}) without external pull-up resistor R_{ext} = 5 kΩ	 V_{Ol} R_{Pup} τ C_L C_L	 39 	 0.08 50 	 0.3 61 2.5 41 540	 V kΩ µs pF pF
POUT output - Saturation voltage LOW - Saturation voltage HIGH	 I_{POUT} = 1 mA I_{POUT} = –1 mA	 V_{Ol} V_{Oh}	 V_S – 0.3V	 0.08 V_S – 0.14V	 0.3 	 V V
FSK/ASK input - Low-level input voltage - High-level input voltage	 FSK selected ASK selected	 V_{Il} V_{Ih}	 0.8 × V_S	 	 0.2 × V_S 	 V V
ENABLE input - Low-level input voltage - High-level input voltage	 Idle mode Active mode	 V_{Il} V_{Ih}	 0.8 × V_S	 	 0.2 × V_S 	 V V
MODE input - Low-level input voltage - High-level input voltage	 Division factor = 10 Division factor = 14	 V_{Il} V_{Ih}	 0.8 × V_S	 	 0.2 × V_S 	 V V
TEST input - Low-level input voltage	Test input must always be set to LOW	V_{Il}			0.2 × V_S	V

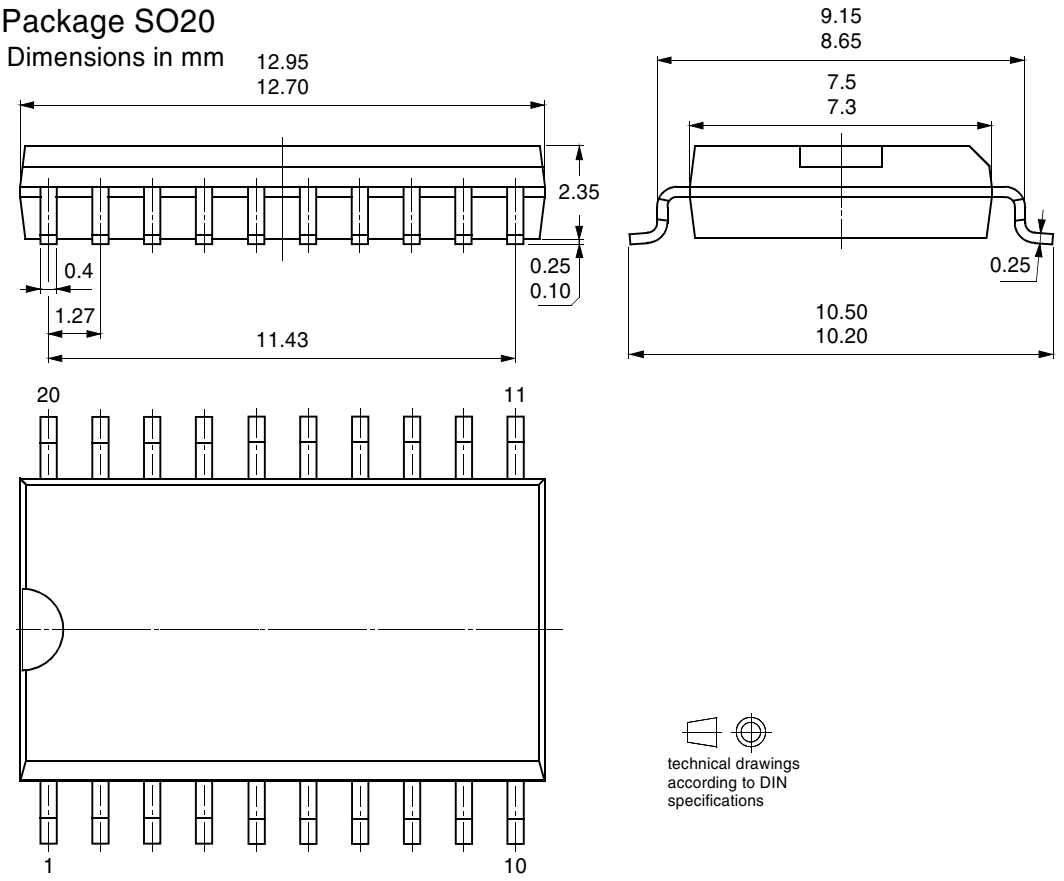
10. Ordering Information

Extended Type Number	Package	Remarks
ATA3741P2-TGSY	SO20	2: IF bandwidth of 300 kHz, tube, Pb-free
ATA3741P2-TGQY	SO20	2: IF bandwidth of 300 kHz, taped and reeled, Pb-free
ATA3741P3-TGSY	SO20	3: IF bandwidth of 600 kHz, tube, Pb-free
ATA3741P3-TGQY	SO20	3: IF bandwidth of 600 kHz, taped and reeled, Pb-free

11. Package Information

Package SO20

Dimensions in mm



12. Revision History

Please note that the following page numbers referred to in this section refer to the specific revision mentioned, not to this document.
